## LAST LECTURE'S THEME

Data Reduction

## THIS LECTURE'S THEME

Dimension Reduction

## MEASURE OF ATTRIBUTE SIMILARITY

Are there attributes that "go together"?

Can you name a few?

## Feature Vector (1)

## Physical attributes

- color
- number of doors
- number of wheels
- retractable roof
- height
- length
- frames around side windows

Which attributes are useful to distinguish SUVs from convertibles?

- number of doors (4 vs. 2) --> numerical, two levels
- retractable roof (no vs. yes) --> categorical, two levels
- frames around side windows (yes vs. no) --> categorical, two levels
- height (higher vs. lower) --> numerical, many levels

## Feature Vector (2)

Which attributes are not so useful?

- number of wheels (constant 4) --> no discriminative power
- length (short and long SUVs, convertibles) --> confounding
- color (colors are seemingly random, or are they?)

Is color useful?

- the convertibles seem to have more vibrant colors (red, yellow, ...)
- so maybe we made a discovery

## Attribute Space

frames around side windows
Need to consider more than two attributes

- height attribute would have distinguished the Range Rover from the convertibles and caused it to be an outlier

## Attribute Space

New classes are constantly evolving over time

- this is known as cluster evolution
- measuring more features will increase the chance of discovery

## HOW Many Data Do We Need?

## The more data (examples) the better

- increases the chances to discover the rare specimen

- but some attributes are useless
- we can cull them away
- perform attribute reduction or dimension reduction

## DIMENSIONALITY REDUCTION

## By axis rotation (linear methods)

- determine a more efficient basis
- Principal Component Analysis (PCA)
- Singular value decomposition (SVD)
- Latent semantic analysis (LSA)

By transformation (non-linear methods)

- determine a more efficient data type
- Fourier analysis and Wavelets for grids
- Multidimensional scaling (MDS) for graphs
- Locally Linear Embedding
- Isomap
- Self Organizing Maps (SOM)
- Linear Discriminant Analysis (LDA)

## PRINCIPAL COMPONENT ANALYSIS (PCA)

## SOME THEORY IS NEEDED

## Covariance

- measures how much two random variables change together

## COVARIANCE

For N variable we have $\mathrm{N}^{2}$ variable pairs

- we can write them in a matrix of size $\mathrm{N}^{2} \rightarrow$ the covariance matrix
- for two variables $X_{1}$ and $X_{2}$

$$
\operatorname{Var}[X]=\left[\begin{array}{cc}
\operatorname{Var}\left[X_{1}\right] & \operatorname{Cov}\left[X_{1}, X_{2}\right] \\
\operatorname{Cov}\left[X_{2}, X_{1}\right] & \operatorname{Var}\left[X_{2}\right]
\end{array}\right]
$$

## FORMULAE

## Covariance $\operatorname{cov}(X, Y)$

mean of all data item values $x_{i}$ and $y_{i}$ for attributes $X$ and $Y$, resp.

$$
\operatorname{cov}(X, Y)=\frac{\sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)\left(Y_{i}-\bar{Y}\right)}{n-1}
$$

Pearson's correlation r

- is covariance normalized by the individual variances for X and Y

$$
r_{x y}=\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sqrt{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} \sum_{i=1}^{n}\left(y_{i}-\bar{x}\right)^{2}}}
$$

individual variances
 for attributes $X$ and $Y$

## CORRELATION PATTERNS

## Correlation rates between -1 and 1 :

Important to note:

- correlation is defined for linear relationships
- visualization can help
- none of these point distributions have correlations:

## COVARIANCE MATRIX

Analytical: $\quad \operatorname{Cov}(X, Y)=E\left[\left(X-\mu_{x}\right)\left(Y-\mu_{y}\right)\right]$
Samples: $\quad \sigma_{x y}=\operatorname{cov}_{x y}=\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)$
An n-D dataset has $n$ variables $x_{1}, x_{2}, \ldots x_{n}$

- define pairwise covariance among all of these variables
- construct a covariance matrix

$$
\mathbf{\Sigma}=\operatorname{Cov}(\mathbf{X})=\left[\begin{array}{cccc}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1 n} \\
\sigma_{21} & \sigma_{22} & \cdots & \sigma_{2 n} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{n 1} & \sigma_{n 2} & \cdots & \sigma_{n n}
\end{array}\right]
$$

- a correlation matrix would just list the correlations instead

## CORRELATION MATRIX

|  | MO | FP | MP | IM | IC | FM | FE | FI | SPC | DSC | DST |

distribution (scatterplot matrix)

## PRINCIPAL COMPONENT ANALYSIS

## Ultimate goal:

- find a coordinate system that can represent the variance in the data with as few axes as possible

- rank these axes by the amount of variance (blue, red)
- drop the axes that have the least variance (red)

## PRINCIPAL COMPONENTS

Find the principal components (factors) of a distribution

First characterize the distribution by

- covariance matrix Cov
- correlation matrix Corr
- lets call it C
- perform QR factorization or LU decomposition to get

$$
\boldsymbol{C}=Q \Lambda Q^{-1}
$$

Q: matrix with Eigenvectors
$\Lambda$ : diagonal matrix with Eigenvalues $\lambda$

- now order the Eigenvectors in terms of their Eigenvalues $\lambda$

## EIGENVECTORS AND VALUES

## COVARIANCE VS. CORRELATION

## When to use what?

- use the covariance matrix when the variable scales are similar
- use the correlation matrix when the variables are on different scales
- the correlation matrix standardizes the data
- in general they give different results, especially when the scales are different

## EXAMPLE

## Before PCA

## EXAMPLE

## After PCA

- $\lambda_{1}=9.8783 \lambda_{2}=3.0308$ Trace $=12.9091$
- PC 1 displays ("explains") 9.8783/12.9091 = 76.5\% of total variance

## How Many Dimensions to Keep?

## Create a scree plot

- plots a histogram of the Eigenvalues ordered by magnitude
- plots the explained variance as a curve

possible threshold
(explain
$75 \%$ of data
variance)

## PCA APPLIED TO FACES

## Take a set of faces:

- each image has $60 \times 60$ pixels
- can write it as a $60 \times 60 \mathrm{D}=3,600 \mathrm{D}$ vector
- space of images is therefore 3600 D
- each image is a point in that space

## Perform PCA

- will yield 3,600 Eigenvectors in 3,600 D space

- each is a face
- called "Eigenfaces"

## PCA APPLIED TO FACES

We can reconstruct a face as a linear combination of these Eigenfaces [M. Turk and A. Pentland (1991)]

Average Face

Eigenfaces

## RECONSTRUCTION USING PCA

$90 \%$ variance is
captured by the first 50 eigenvectors
Reconstruct existing faces using only 50 basis images

reconstructed with 50 eigenfaces

We can also generate new faces by combining
eigenvectors with different weights

## Problem WITH PCA

The axes of the space generated by PCA do not mean much semantically

- the Eigenvectors are combinations of the actual data dimensions
- can we use these to determine the most important data dimensions which would be more meaningful?
- we shall explain it via an example
- see next slides

## A More Challenging Example

- Data from research on habitat definition of the endangered Baw Baw frog
- 16 environmental and structural variables measured at each of 124 sites
- Correlation matrix used because variables have different units

## Eigenvalues

| Axis | Eigenvalue | \% of <br> Variance | Cumulative \% <br> of Variance |
| :---: | :---: | :---: | :---: |
| 1 | 5.855 | 36.60 | 36.60 |
| 2 | 3.420 | 21.38 | 57.97 |
| 3 | 1.122 | 7.01 | 64.98 |
| 4 | 1.116 | 6.97 | 71.95 |
| 5 | 0.982 | 6.14 | 78.09 |
| 6 | 0.725 | 4.53 | 82.62 |
| 7 | 0.563 | 3.52 | 86.14 |
| 8 | 0.529 | 3.31 | 89.45 |
| 9 | 0.476 | 2.98 | 92.42 |
| 10 | 0.375 | 2.35 | 94.77 |

## How Many Axes Are Needed?

- Does the $(k+1)^{\text {th }}$ principal axis represent more variance than would be expected by chance?
- Several tests and rules have been proposed
- A common "rule of thumb" when PCA is based on correlations is that axes with eigenvalues > 1 are worth interpreting
- In our example 4 Eigenvectors fit this criterion (we shall keep 3 for simplicity)

## Baw Baw Frog - PCA of 16 Habitat Variables

## Interlude - What's a "Loading"?

- The amount of weight a data dimension has on a principal component
- petal length/width have a high loading on PC1
- sepal width has a high loading on PC2
- Another observation
- projection into PC basis can also bring out clusters better
- since spread is maximized

## Interpreting Eigenvectors

- Correlations between variables and the principal axes are known as loadings
- Each element of the eigenvectors represents the contribution of a given variable to a component
The loadings of variables on the first three PCs are shown here

|  | PC 1 | PC 2 | PC 3 |
| :--- | :---: | :---: | :---: |
| Altitude | 0.3842 | 0.0659 | -0.1177 |

| DistMF | 0.3899 | 0.0586 | -0.0175 |

## Significance of Variables

We can compute the significance of the variables as the sum of squared loadings on to the most significant Eigenvectors we selected (3 in our example)
The next slide shows the table of the last slide expanded with these squared loadings
We can then sort the table by the squared loadings and make a scree plot
The most significant variables are those above some chosen cutoff, for example 0.4 (marked in yellow in the table)

## Significance of Variables

|  | PC 1 | PC 2 | PC 3 | sum of squared <br> loadings (sqrt) |
| :--- | :---: | :---: | :---: | :---: |
| Altitude | 0.3842 | 0.0659 | -0.1177 | 0.41 |
| pH | -0.1159 | 0.1696 | -0.5578 | 0.59 |
| Cond | -0.2729 | -0.1200 | 0.3636 | 0.47 |
| TempSurf | 0.0538 | -0.2800 | 0.2621 | 0.39 |

| DistMF | 0.3899 | 0.0586 | -0.0175 | 0.39 |

## Significance of Variables

- Scree plot

variables considered significant
more aggressive reduction of variables
chosen significance threshold
only eliminate very weak variables

## SUMMARY

## Learned about:

- feature vectors, each feature is a data attribute, dimension
- distinguish useful from not so useful features with regards to data discrimination $\rightarrow$ dimension reduction
- plot data into feature space and observe clusters
- correlation vs. covariance
- algorithmic dimension reduction, summary of popular dimension reduction schemes - linear vs. non-linear
- basic linear scheme: Principal Component Analysis (PCA)
- application of PCA to face detection and generation
- scree plot to visualize and select the most important PCA axes
- use of PCA loading analysis to determine the most significant data features
