CDMA

• Code division multiplexing: different users use different languages.
• CDMA: code division multiple access.

• How to find good codes?
• How to separate the signal from other signals and noise?
CDMA

- CDMA (Code Division Multiple Access)
  - all terminals send on the same frequency probably at the same time and can use the whole bandwidth of the transmission channel
  - each sender has a unique random number, the sender XORs the signal with this random number
  - the receiver can “tune” into this signal if it knows the pseudo random number, tuning is done via a correlation function
CDMA

• Disadvantages:
  – higher complexity of a receiver (receiver cannot just listen into the medium and start receiving if there is a signal)
  – all signals should have the same strength at a receiver

• Advantages:
  – all terminals can use the same frequency, no planning needed
  – huge code space (e.g. $2^{32}$) compared to frequency space
  – interferences (e.g. white noise) is not coded
  – forward error correction and encryption can be easily integrated
Example: DSSS

- DSSS (Direct Sequence Spread Spectrum)
- The code: chipping sequence.

\[ \text{0 1 1 0 1 0 1 0 1 0 0 1 1} \]

\[ \text{0 1 1 0 0 1 0 1 1 0 1 0 0 1} \]

\[ \text{0 1 1 0 1 0 1 0 1 1 0 0 1 0 1 0} \]

\[ t_b : \text{bit period} \]
\[ t_c : \text{chip period} \]
What is a good code?

• A code is a vector, each bit is 1 or -1.
  – 10110111000 is (1,-1,1,1,-1,1,1,1,-1,-1,-1).

• Good autocorrelation
  – $a\cdot a$ is large.

• Orthogonal to other codes
  – $a\cdot b$ is zero.

• Why is this helpful?
An example

• Sender A
  – sends $A_d = 1$, key $A_k = 010011$ (assign: „0“ = -1, „1“ = +1)
  – sending signal $A_s = A_d * A_k = (-1, +1, -1, -1, +1, +1)$

• Sender B
  – sends $B_d = 0$, key $B_k = 110101$ (assign: „0“ = -1, „1“ = +1)
  – sending signal $B_s = B_d * B_k = (-1, -1, +1, -1, +1, -1)$
Receiver

• Both signals superimpose in space
  – interference neglected (noise etc.)
  – $A_s + B_s = (-2, 0, 0, -2, +2, 0)$

• Receiver wants to receive signal from sender A
  – apply key $A_k$ bitwise (inner product)
    • $A_e = (-2, 0, 0, -2, +2, 0) \bullet A_k = 2 + 0 + 0 + 2 + 2 + 0 = 6$
    • result greater than 0, therefore, original bit was „1“
  – receiving B
    • $B_e = (-2, 0, 0, -2, +2, 0) \bullet B_k = -2 + 0 + 0 - 2 - 2 + 0 = -6$, i.e. „0“
Receiver

• We did several simplifications:
  – No noise.
  – Signal strength are the same.
  – Perfectly superimpose.
• Assume B’s signal strength is 5 times larger.
  – \( A_s + 5B_s = (-6, -4, 4, -6, +6, -4) \)
• Receiver wants to receive signal from sender A
  – apply key \( A_k \) bitwise (inner product)
    • \( A_e = (-6, -4, 4, -6, +6, -4) \)
    • \( A_k = 6 \)
  – receiving B
    • \( B_e = (-6, -4, 4, -6, +6, -4) \)
    • \( B_k = -30 \)

CDMA

• Good against tapping: the adversary does not know the chipping sequence.
• Why the chipping sequence is also called a key.

• Precise power control – waste a lot of energy.
• It requires the mutual agreement on a key.
• Cellular phone system: base stations take charge of key establishment.
• For spontaneous communication, the key establishment is too much overhead.
SAMA - Spread Aloha Multiple Access

• Aloha + CDMA
• Use the same code, but compete for the medium.
• Aloha has only a very low efficiency, CDMA needs complex receivers to be able to receive different senders with individual codes at the same time
• Idea: use spread spectrum with only one single code (chipping sequence) for spreading for all senders accessing according to aloha
SAMA - Spread Aloha Multiple Access

Problem: find a chipping sequence with good characteristics

spread the signal e.g. using the chipping sequence 110101 ("CDMA without CD")

sender A
sender B

narrow band
send for a shorter period with higher power

<th>FDMA</th>
<th>CDMA</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Idea</strong></td>
<td>segment space into cells/sectors</td>
<td>segment sending time into disjoint time-slots, demand driven or fixed patterns</td>
<td>segment the frequency band into disjoint sub-bands</td>
<td>spread the spectrum using orthogonal codes</td>
</tr>
<tr>
<td><strong>Terminals</strong></td>
<td>only one terminal can be active in one cell/one sector</td>
<td>all terminals are active for short periods of time on the same frequency</td>
<td>every terminal has its own frequency, uninterrupted</td>
<td>all terminals can be active at the same place at the same moment, uninterrupted</td>
</tr>
<tr>
<td><strong>Signal separation</strong></td>
<td>cell structure, directed antennas</td>
<td>synchronization in the time domain</td>
<td>filtering in the frequency domain</td>
<td>code plus special receivers</td>
</tr>
<tr>
<td><strong>Advantages</strong></td>
<td>very simple, increases capacity per km²</td>
<td>established, fully digital, flexible</td>
<td>simple, established, robust</td>
<td>flexible, less frequency planning needed, soft handover</td>
</tr>
<tr>
<td><strong>Disadvantages</strong></td>
<td>inflexible, antennas typically fixed</td>
<td>guard space needed (multipath propagation), synchronization difficult</td>
<td>inflexible, frequencies are a scarce resource</td>
<td>complex receivers, needs more complicated power control for senders</td>
</tr>
<tr>
<td><strong>Comment</strong></td>
<td>only in combination with TDMA, FDMA or CDMA useful</td>
<td>standard in fixed networks, together with FDMA/SDMA used in many mobile networks</td>
<td>typically combined with TDMA (frequency hopping patterns) and SDMA (frequency reuse)</td>
<td>still faces some problems, higher complexity, lowered expectations; will be integrated with TDMA/FDMA</td>
</tr>

Wireless LAN
This chapter

• We’ve covered how to communicate between each pair of users.
• Now we have many users and put them together in a system.
• Architecture: how to organize them?
Infrastructure-based networks

infrastructure network

wired network

AP: Access Point
Ad hoc networks
Infrastructure v.s. ad hoc

- Infrastructure-based
  - Communication only between access points and wireless nodes.
  - Access point decide on MAC, and forwarding.
  - Easy to organize.
  - Most functionalities lies within the access point.
  - Clients are simple.
  - Less flexible, not in disaster relief.
  - Cellular networks, satellite based networks.
  - 802.11 Wireless LAN
Infrastructure v.s. ad hoc

• Ad hoc networks
  – Flexible, suitable for emergent situation.
  – Nodes self-organize into a network.
  – The complexity of each node is higher.
  – Each node handles MAC, hidden/exposed terminal problems.
  – Bluetooth.

• Hybrid networks
Mobile Communication Technology according to IEEE

Local wireless networks
- **WLAN** 802.11
  - **WiFi**
    - 802.11a → 802.11h
    - 802.11b → 802.11g
    - 802.11i/e/…/w

Personal wireless nw
- **WPAN** 802.15
  - **ZigBee**
    - 802.15.4 → 802.15.4a/b
    - 802.15.5
    - 802.15.1 → 802.15.2 → 802.15.3 → 802.15.3a/b

Wireless distribution networks
- **WMAN** 802.16 (Broadband Wireless Access)
  - **WiMAX**
    - + Mobility
    - 802.20 (Mobile Broadband Wireless Access)
Characteristics of wireless LANs

• Advantages
  – very flexible within the reception area
  – Ad-hoc networks without previous planning possible
  – (almost) no wiring difficulties (e.g. historic buildings, firewalls)
  – more robust against disasters like, e.g., earthquakes, fire - or users pulling a plug...

• Disadvantages
  – typically very low bandwidth compared to wired networks (1-10 Mbit/s) due to shared medium
  – many proprietary solutions, especially for higher bit-rates, standards take their time (e.g. IEEE 802.11)
  – products have to follow many national restrictions if working wireless, it takes a vary long time to establish global solutions like, e.g., IMT-2000
Design goals for wireless LANs

- global, seamless operation
- low power for battery use
- no special permissions or licenses needed to use the LAN
- robust transmission technology
- simplified spontaneous cooperation at meetings
- easy to use for everyone, simple management
- protection of investment in wired networks
- security (no one should be able to read my data), privacy (no one should be able to collect user profiles), safety (low radiation)
- transparency concerning applications and higher layer protocols, but also location awareness if necessary
Comparison: infrared vs. radio transmission

- **Infrared**
  - uses IR diodes, diffuse light, multiple reflections (walls, furniture etc.)
- **Advantages**
  - simple, cheap, available in many mobile devices
  - no licenses needed
  - simple shielding possible
- **Disadvantages**
  - interference by sunlight, heat sources etc.
  - many things shield or absorb IR light
  - low bandwidth
- **Example**
  - IrDA (Infrared Data Association) interface available everywhere

- **Radio**
  - typically using the license free ISM band at 2.4 GHz
- **Advantages**
  - experience from wireless WAN and mobile phones can be used
  - coverage of larger areas possible (radio can penetrate walls, furniture etc.)
- **Disadvantages**
  - very limited license free frequency bands
  - shielding more difficult, interference with other electrical devices
- **Example**
  - Many different products
802.11 - Architecture of an infrastructure network

- **Station (STA)**
  - terminal with access mechanisms to the wireless medium and radio contact to the access point

- **Basic Service Set (BSS)**
  - group of stations using the same radio frequency

- **Access Point**
  - station integrated into the wireless LAN and the distribution system

- **Portal**
  - bridge to other (wired) networks

- **Distribution System**
  - interconnection network to form one logical network (EES: Extended Service Set) based on several BSS
802.11 - Architecture of an ad-hoc network

- Direct communication within a limited range
  - Station (STA): terminal with access mechanisms to the wireless medium
  - Independent Basic Service Set (IBSS): group of stations using the same radio frequency

802.11 - Physical layer (classical)

- 3 versions: 2 radio (typ. 2.4 GHz), 1 IR
  - data rates 1 or 2 Mbit/s
- FHSS (Frequency Hopping Spread Spectrum)
  - spreading, despreading, signal strength, typ. 1 Mbit/s
  - min. 2.5 frequency hops/s (USA), two-level GFSK modulation
- DSSS (Direct Sequence Spread Spectrum)
  - DBPSK modulation for 1 Mbit/s (Differential Binary Phase Shift Keying), DQPSK for 2 Mbit/s (Differential Quadrature PSK)
  - preamble and header of a frame is always transmitted with 1 Mbit/s, rest of transmission 1 or 2 Mbit/s
  - chipping sequence: +1, -1, +1, +1, -1, +1, +1, -1, -1, -1 (Barker code)
  - max. radiated power 1 W (USA), 100 mW (EU), min. 1mW
- Infrared
  - 850-950 nm, diffuse light, typ. 10 m range
  - carrier detection, energy detection, synchronization
FHSS PHY packet format

- Synchronization
  - synch with 010101... pattern
- SFD (Start Frame Delimiter)
  - 0000110010111101 start pattern
- PLW (PLCP_PDU Length Word)
  - length of payload incl. 32 bit CRC of payload, PLW < 4096
- PSF (PLCP Signaling Field)
  - data of payload (1 or 2 Mbit/s)
- HEC (Header Error Check)
  - CRC with $x^{16} + x^{12} + x^5 + 1$
DSSS PHY packet format

- **Synchronization**
  - synch., gain setting, energy detection, frequency offset compensation

- **SFD (Start Frame Delimiter)**
