Introduction to
Programming in C
Control Flow Revisited

Spring 2018

Stony Brook University

Instructor: Shebuti Rayana

Control Flow

■ Program Control

- Program begins execution at the `main()` function.
- Statements within the `main()` function are then executed from top-down style, line-by-line.
- However, this order is rarely encountered in real C program.
- The order of the execution within the `main()` body may be branched.
- Changing the order in which statements are executed is called program control.
- Accomplished by using program **control flow statements**.
- So we can control the program flows.

Control Flow

- There are three types of program controls:
 1. **Sequence** *control structure*.
 2. **Selection** *structures such as `if`, `if-else`, `nested if`, `if-if-else`, `if-else-if` and `switch-case-break`.*
 3. **Repetition** *(loop) such as `for`, `while` and `do-while`.*
- Certain C functions and keywords also can be used to control the program flows.

Sequence

- Take a look at the following example

```
#include <stdio.h> // put stdio.h file here

int main(void)
{
    float paidRate = 5.0, sumPaid, paidHours = 25;
    sumPaid = paidHours * paidRate;
    printf("Paid sum = $%.2f \n", sumPaid);
    return 0;
}
```

printf("...")
definition

Jump/branch to printf()

Back to main() from printf()

Sequence

<code>float paidRate=5.0, sumPaid, paidHours=25;</code>	S1
<code>sumPaid = paidHours * paidRate;</code>	S2
<code>printf("Paid sum = \$%.2f \n", sumPaid);</code>	S3
<code>return 0;</code>	S4

- One entry point and one exit point.
- Conceptually, a control structure like this means a sequence execution.

Selection Control Flow

- Program need to select from the options given for execution.
- At least 2 options, can be more than 2.
- Option selected based on the *condition* evaluation result: TRUE or FALSE.

Selection: most basic `if`

<code>if (condition)</code>	<code>if (condition)</code>
<code>statement;</code>	<code>{ statements; }</code>
<code>next_statement;</code>	<code>next_statement;</code>

1. `(condition)` is evaluated.
2. If `TRUE` (non-zero) the `statement` is executed.
3. If `FALSE` (zero) the `next_statement` following the `if` statement block is executed.
4. So, during the execution, based on some condition, some codes were skipped.

Example: `if`

For example:

```
if (hours > 70)
    hours = hours + 100;
printf("Less hours, no bonus!\n");
```

- If `hours` is less than or equal to 70, its value will remain unchanged and only `printf()` will be executed.
- If it exceeds 70, its value will be increased by 100 and then `printf()` will be executed.

Selection: `if-else`

<code>if (condition)</code>	<code>if (condition)</code>
<code> statement_1;</code>	<code> { a block of statements;}</code>
<code>else</code>	<code>else</code>
<code> statement_2;</code>	<code> { a block of statements;}</code>
<code>next_statement;</code>	<code>next_statement;</code>

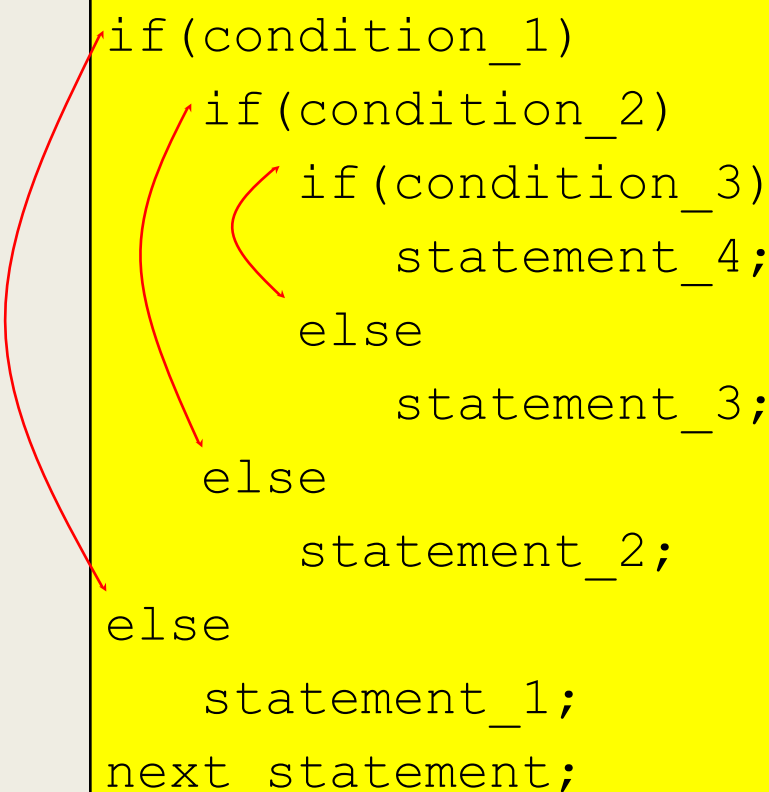

Explanation:

1. The `(condition)` is evaluated.
2. If it evaluates to non-zero (TRUE), `statement_1` is executed, otherwise, if it evaluates to zero (FALSE), `statement_2` is executed.
3. They are mutually exclusive, meaning, either `statement_1` is executed or `statement_2`, but not both.
4. `statements_1` and `statements_2` can be a block of codes and must be put in curly braces.

Selection: Nested `if-else`

- The `if-else` constructs can be nested (placed one within another) to any depth.
- General forms: `if-if-else` and `if-else-if`.
- Following is `if-if-else` constructs (3 level of depth)

```
if(condition_1)
    if(condition_2)
        if(condition_3)
            statement_4;
        else
            statement_3;
    else
        statement_2;
else
    statement_1;
next_statement;
```

Selection: Nested `if-else`

- The `if-else-if` statement has the following form (3 levels example).

```
if(condition_1)
    statement_1;
else if (condition_2)
    statement_2;
else if(condition_3)
    statement_3;
else
    statement_4;
next_statement;
```

Selection: `switch-case-break`

- The most flexible selection program control.
- Enables the program to execute different statements based on an condition or expression that can have more than two values.
- Also called multiple choice statements.
- The if statement were limited to evaluating an expression that could have only two logical values: TRUE or FALSE.
- If more than two values, have to use nested if.
- The `switch` statement makes such nesting unnecessary.
- Used together with `case` and `break`.

Selection: switch-case-break

```
switch(condition)
{
    case template_1 : statement(s);
                    break;
    case template_2 : statement(s);
                    break;
    case template_3 : statement(s);
                    break;
    ...
    ...
    case template_n : statement(s);
                    break;

    default : statement(s);
}
next_statement;
```

The Conditional Operator

- General form: $expr_1 ? expr_2 : expr_3 ;$
- If $expr_1$ is true, the conditional statement's value is that of $expr_2$; otherwise, its value is that of $expr_3$
- This operator can be confusing to look at

Equivalent Code

```
if (y < z)
```

```
    x = y;
```

```
else
```

```
    x = z;
```

```
x = (y < z) ? y : z;
```

Repetition: `for` loop

- Executes a code block for a certain number of times.
- Code block may have no statement, one statement or more.
- `for` loop executes a fixed number of times.

```
for(initial_value;condition(s);increment/decrement)
    statement(s);
next_statement;
```

- `initial_value`, `condition(s)` and `increment/decrement` are any valid C expressions.
- The `statement(s)` may be a single or compound C statement (a block of code).
- When `for` statement is encountered during program execution, the following events occurs:
 1. The `initial_value` is evaluated e.g. `intNum = 1`.
 2. Then the `condition(s)` is evaluated, typically a relational expression.
 3. If `condition(s)` evaluates to `FALSE` (zero), the `for` statement terminates and execution passes to `next_statement`.
 4. If `condition(s)` evaluates as `TRUE` (non zero), the `statement(s)` is executed.
 5. Next, `increment/decrement` is executed, and execution returns to step no. 2 until `condition(s)` becomes `FALSE`.

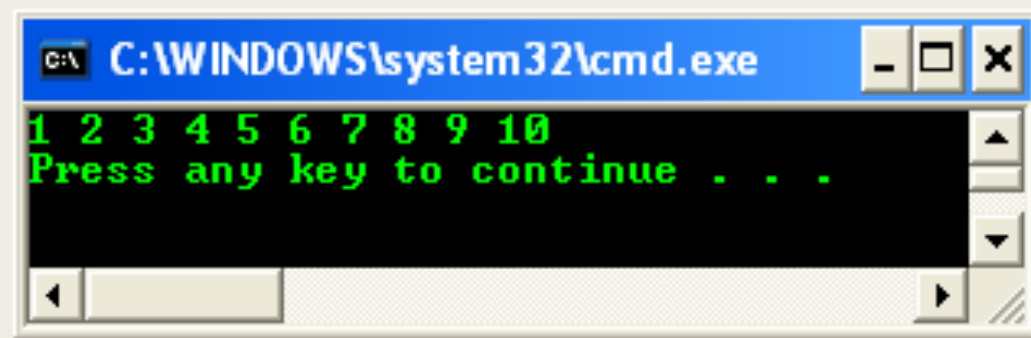

Flow Chart: `for` loop

Example: for loop

- A Simple for example, printing integer 1 to 10.

```
#include <stdio.h>
void main(void)
{
    int nCount;
    // display the numbers 1 to 10
    for(nCount = 1; nCount <= 10; nCount++)
        printf("%d ", nCount);
    printf("\n");
}
```

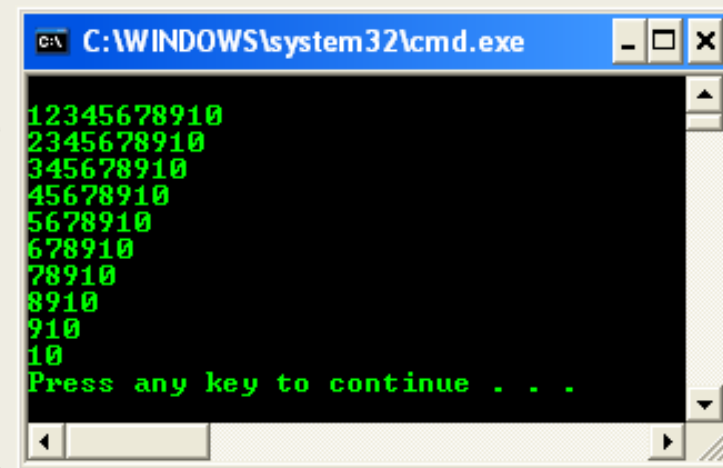

```
C:\WINDOWS\system32\cmd.exe
1 2 3 4 5 6 7 8 9 10
Press any key to continue . . .
```

Nested for loop

- for loops can be nested

```
for(initial_value;condition(s);increment/decrement) {  
    for(initial_value;condition(s);increment/decrement) {  
        statement(s);  
    }  
}  
next_statement;
```

- For this output the program has two for loops.
- The loop index `iRow` for the outer (first) loop runs from 1 to 10 and for each value of `iRow`, the loop index `jColumn` for the inner loop runs from `iRow + 1` to 10.
- Note that for the last value of `iRow` (i.e. 10), the inner loop is not executed at all because the starting value of `jColumn` is 11 and the expression `jColumn < 11` yields the value false (`jColumn = 11`).

```
C:\WINDOWS\system32\cmd.exe  
12345678910  
2345678910  
345678910  
45678910  
5678910  
678910  
78910  
8910  
910  
10  
Press any key to continue . . .
```

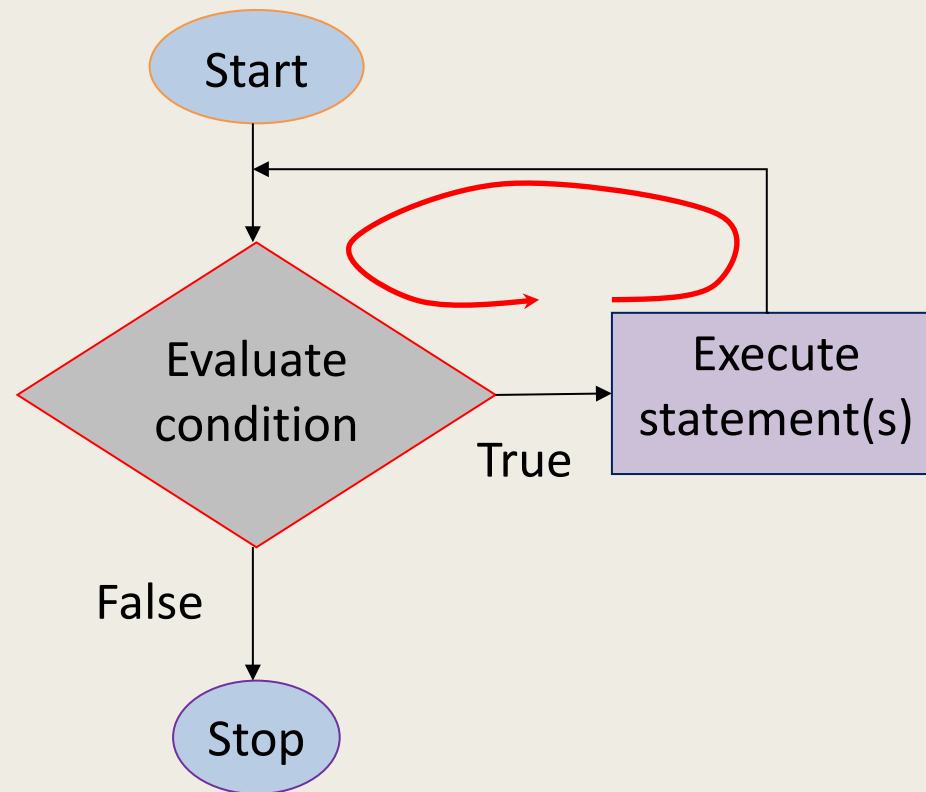

Repetition: `while` loop

- Executes a block of statements as long as a specified condition is `TRUE`.

```
while (condition)
    statement(s);
next_statement;
```

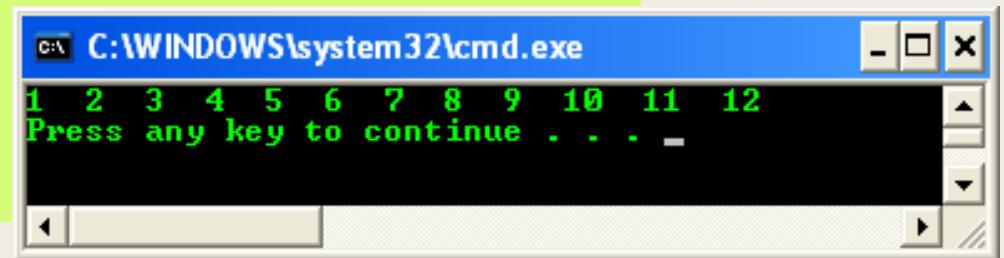

- The `(condition)` may be any valid C expression.
- The `statement(s)` may be either a single or a compound (a block of code) C statement.
- When `while` statement encountered, the following events occur:
 1. The `(condition)` is evaluated.
 2. If `(condition)` evaluates to `FALSE` (zero), the `while` loop terminates and execution passes to the `next_statement`.
 3. If `(condition)` evaluates as `TRUE` (non zero), the C `statement(s)` is executed.
 4. Then, the execution returns to step number 1 until condition becomes `FALSE`.

Flow Chart: `while` loop

Example: while loop

```
// simple while loop example
#include <stdio.h>
int main(void)
{
    int nCalculate = 1;
    // set the while condition
    while(nCalculate <= 12)
    {
        // print
        printf("%d ", nCalculate);
        // increment by 1, repeats
        nCalculate++;
    }
    // a newline
    printf("\n");
    return 0;
}
```

A screenshot of a Windows command prompt window. The title bar reads "C:\WINDOWS\system32\cmd.exe". The window contains the output of the program: "1 2 3 4 5 6 7 8 9 10 11 12" followed by "Press any key to continue . . .". The cursor is positioned at the end of the second line of output.

for vs while loop

- The same task that can be performed using the `for` statement.
- But, `while` statement does not contain an initialization section, the program must explicitly initialize any variables beforehand.
- As conclusion, `while` statement is essentially a `for` statement without the initialization and increment components.
- `While` can be nested like `for`
- The syntax comparison between `for` and `while`,

```
for( ; condition; ) vs while(condition)
```

Repetition: do-while loop

- Executes a block of statements if the condition is true at least once.
- Test the condition at the end of the loop rather than at the beginning

```
do
    statement (s) ;
while (condition)
next_statement;
```

- (condition) can be any valid C expression.
- statement (s) can be either a single or compound (a block of code) C statement.
- When the program encounter the do-while loop, the following events occur:
 1. The statement (s) are executed.
 2. The (condition) is evaluated. If it is TRUE, execution returns to step number 1. If it is FALSE, the loop terminates and the next_statement is executed.
 3. This means the statement (s) in the do-while will be executed at least once.

Flow Chart: do-while loop

- The statement(s) are always executed at least once.
- `for` and `while` loops evaluate the condition at the start of the loop, so the associated statements are not executed if the condition is initially `FALSE`.

break statement

- The `break` statement causes an exit from the innermost enclosing loop or switch statement.

```
while (1) {
    scanf("%lf", &x);
    if (x < 0.0) /* exit loop if x is negative */
        break;
    printf("%f\n", sqrt(x));
}
/* break jumps to here */
```

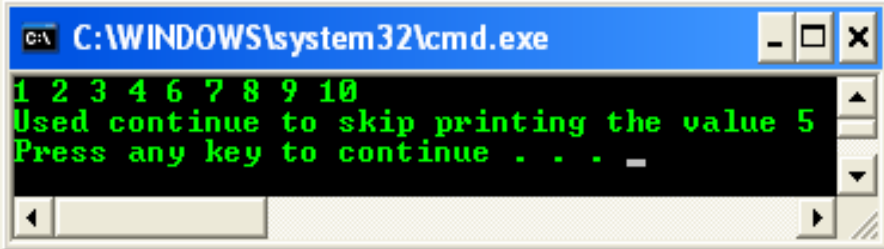

continue statement

- `continue` keyword forces the next iteration to take place immediately, skipping any instructions that may follow it.
- The `continue` statement can only be used inside a loop (`for`, `do-while` and `while`) and not inside a `switch-case` selection.
- When executed, it transfers control to the condition (the expression part) in a `while` or `do-while` loop, and to the increment expression in a `for` loop.
- Unlike the `break` statement, `continue` does not force the termination of a loop, it merely transfers control to the next iteration.

Example: continue statement

```
// using the continue in for structure
#include <stdio.h>

int main(void)
{
    int iNum;
    for(iNum = 1; iNum <= 10; iNum++)
    {
        // skip remaining code in loop only if iNum == 5
        if(iNum == 5)
            continue;
        printf("%d ", iNum);
    }
    printf("\nUsed continue to skip printing the value 5\n");
    return 0;
}
```

```
C:\WINDOWS\system32\cmd.exe
1 2 3 4 6 7 8 9 10
Used continue to skip printing the value 5
Press any key to continue . . . -
```

goto statement

- The `goto` statement is one of C **unconditional jump** or branching.
- When `goto` statement is encountered, execution jumps, or branches, to the location specified by `goto`.
- The branching does not depend on any condition.
- `goto` statement and its target label must be located in the same function, although they can be in different blocks.
- Use `goto` to transfer execution both into and out of loop.
- However, using `goto` statement strongly not recommended. Always use other C branching statements.
- When program execution branches with a `goto` statement, no record is kept of where the execution is coming from.

Example: goto statement

```
while (scanf("%lf", &x) == 1) {  
    if (x < 0.0)  
        goto negative_alert;  
    printf("%f %f\n", sqrt(x) , sqrt(2 * x));  
}  
negative_alert: printf("Negative value encountered!\n");
```

return statement

- The `return` statement has a form,

return expression;

- The action is to terminate execution of the current function and pass the value contained in the expression (if any) to the function that invoked it.
- The value returned must be of the same type or convertible to the same type as the function's return type (type casting).
- More than one return statement may be placed in a function.
- The execution of the first `return` statement in the function automatically terminates the function.

Program Control

Callee

printf("...") definition

Caller

```
#include <stdio.h>
int main(void)
{
    int nNum = 20;
    printf("Initial value of the nNum variable is %d", nNum);
    return 0;
}
```
