11/2/2017    **TLS**

Michalis Polychronakis  
*Stony Brook University*

# **TLS** (Transport Layer Security)

Predecessor: **SSL** (Secure Socket Layer)

Most widely used protocol for encrypted data transmission

Same basic design, different crypto algorithms

Designed to provide secure communication over the insecure internet

Authentication, confidentiality, and integrity

Used in many services and secure versions of protocols

HTTP, POP, IMAP, SMTP, OpenVPN, CalDAV, CardDAV, LDAP, NNTP, FTP, IRC, SIP, ...

Separate port number: HTTPS: 443, FTPS: 990, IMAPS: 993, ...

# History

## SSL developed at Netscape

- v1: never released
- v2 (1994): serious weaknesses
- v3 (1995): re-design, basis of what we use today

NETSCAPE®

## TLS working group was formed to migrate SSL to IETF

- TLS 1.0 (1999): minor differences but incompatible with SSL 3 (different crypto algorithms)
- TLS 1.1 (2006): mostly security fixes, TLS extensions
- TLS 1.2 (2008): authenticated encryption, more flexible
- TLS 1.3 (WiP): removal of legacy/weak algorithms, lower latency

## Endless cycle of vulnerabilities and improvements

Insecure renegotiation, RC4 weaknesses, compression side channels, padding oracle attacks, buggy implementations, PKI attacks, ...

Lately with fancy names, too: *BEAST, CRIME, TIME, Lucky 13, BREACH, POODLE, FREAK, Heartbleed, DROWN, ...*

## **Handshake protocol**

Negotiate session keys and crypto algorithms to be used

Authentication (server and optionally client)

Takes 6–10 messages, depending on features used

## **Record Protocol**

*Message transport:* [header | data] records (16K)

*Encryption and integrity:* after handshake completion

*Compression:* before encryption... not a good idea

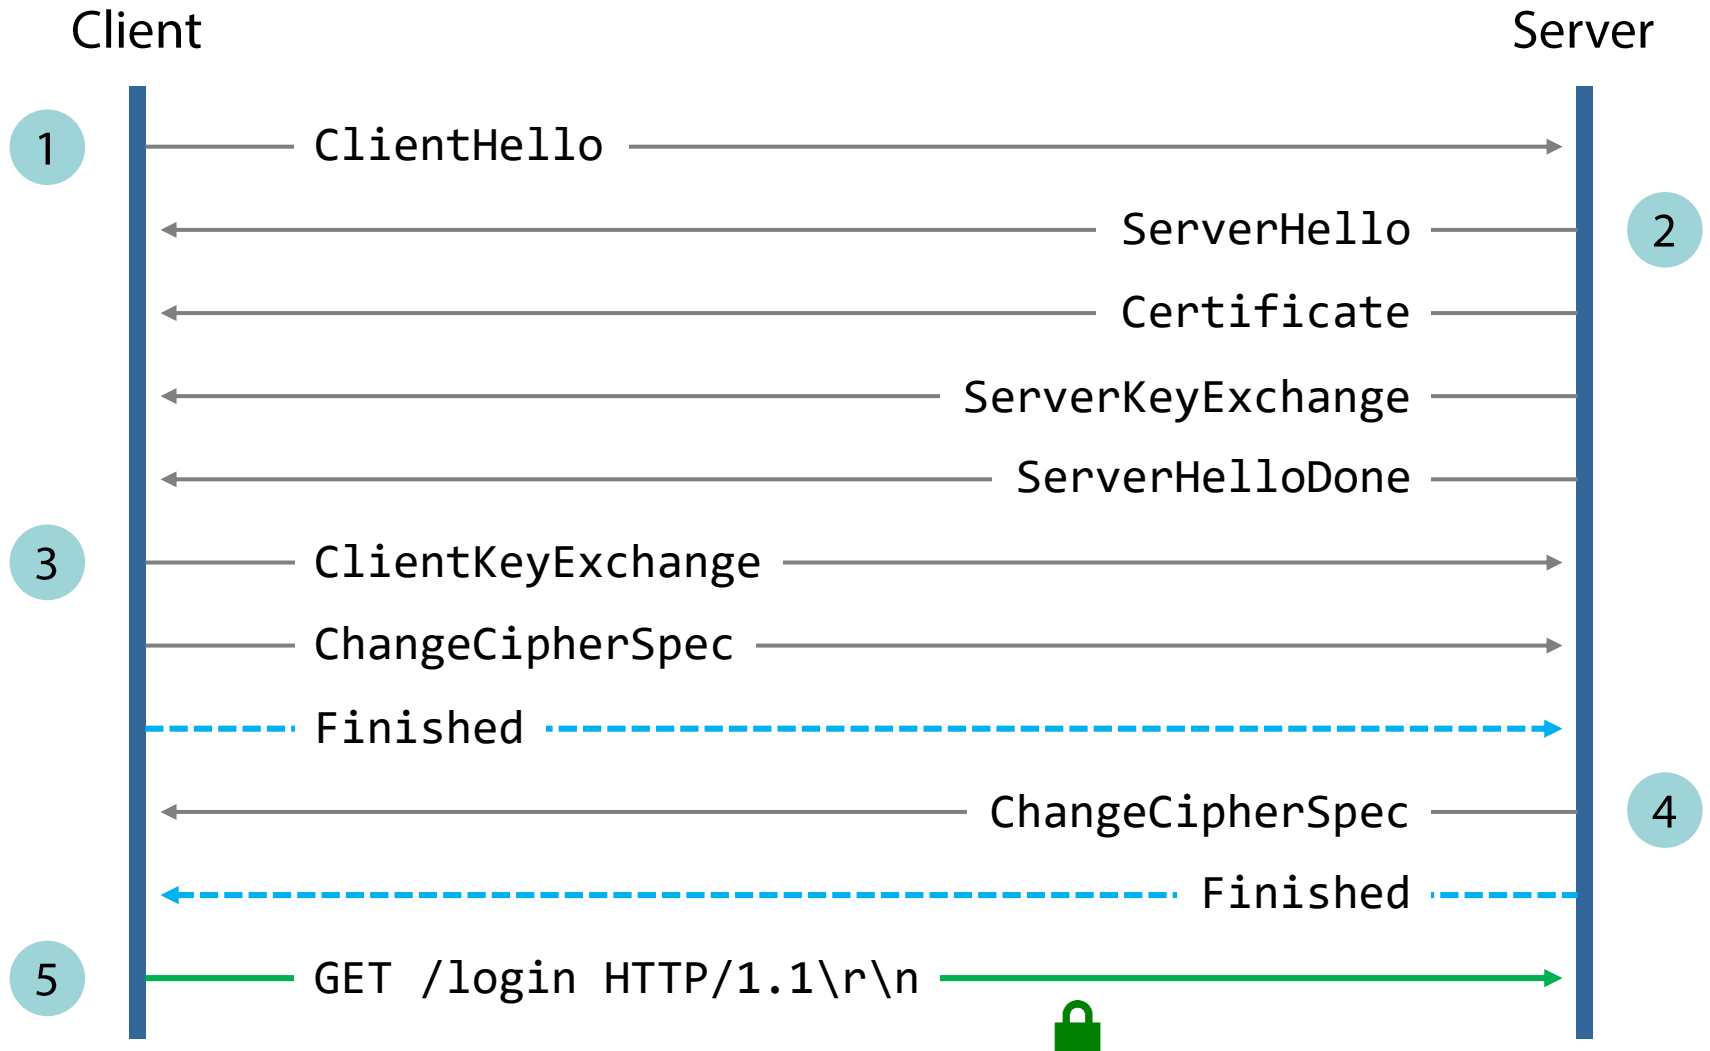

Side-channel attacks (e.g., CRIME)

*Subprotocols:* allow for extensibility

TLS defines four core subprotocols:

*handshake, change cipher spec, application data, alert*

# TLS 1.2 Handshake (Ephemeral DH)

# Cipher Suite Negotiation

ClientHello: *here are the cipher suites I support*

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256

TLS\_DHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256

TLS\_RSA\_WITH\_AES\_128\_GCM\_SHA256

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA

TLS\_DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA

TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA

TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA

TLS\_RSA\_WITH\_RC4\_128\_SHA

...

ServerHello: *let's use this one*

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256

The server might not support the best of the client's suites

Offers some other version hoping that the client will accept it

# Downgrade Attacks

Force a weaker cipher suite selection through MitM

SSL 2: no handshake integrity

SSL 3: protocol rollback protection (still breakable)

TLS 1.0 and on: additional protections

Due to server bugs and interoperability issues, browsers responded by voluntarily downgrading the protocol upon handshake failure

Retrying connection with lower SSL/TLS version

Attackers can exploit this by blocking the initial handshake attempts

Or modify the client's list of supported clients (and include only weak ones)

# SSL 3.0 is now completely removed by most browsers

TLS/SSL support history of web browsers

Browser	Version	Platforms	SSL protocols		TLS protocols				Certificate Support			Vulnerabilities fixed <sup>[n 1]</sup>					Protocol selection by user <sup>[n 2]</sup>	
			SSL 2.0 (insecure)	SSL 3.0 (insecure)	TLS 1.0	TLS 1.1	TLS 1.2	TLS 1.3 (proposed)	EV <sup>[n 3][48]</sup>	SHA-2 <sup>[49]</sup>	ECDSA <sup>[50]</sup>	BEAST <sup>[n 4]</sup>	CRIME <sup>[n 5]</sup>	POODLE (SSLv3) <sup>[n 6]</sup>	RC4 <sup>[n 7]</sup>	FREAK <sup>[51][52]</sup>		Logjam

## TLS 1.2 Session Resumption

Full handshake: 6-10 messages and two network round-trips

Along with CPU-intensive crypto operations, cert validation, ...

Avoid re-negotiation by remembering security parameters

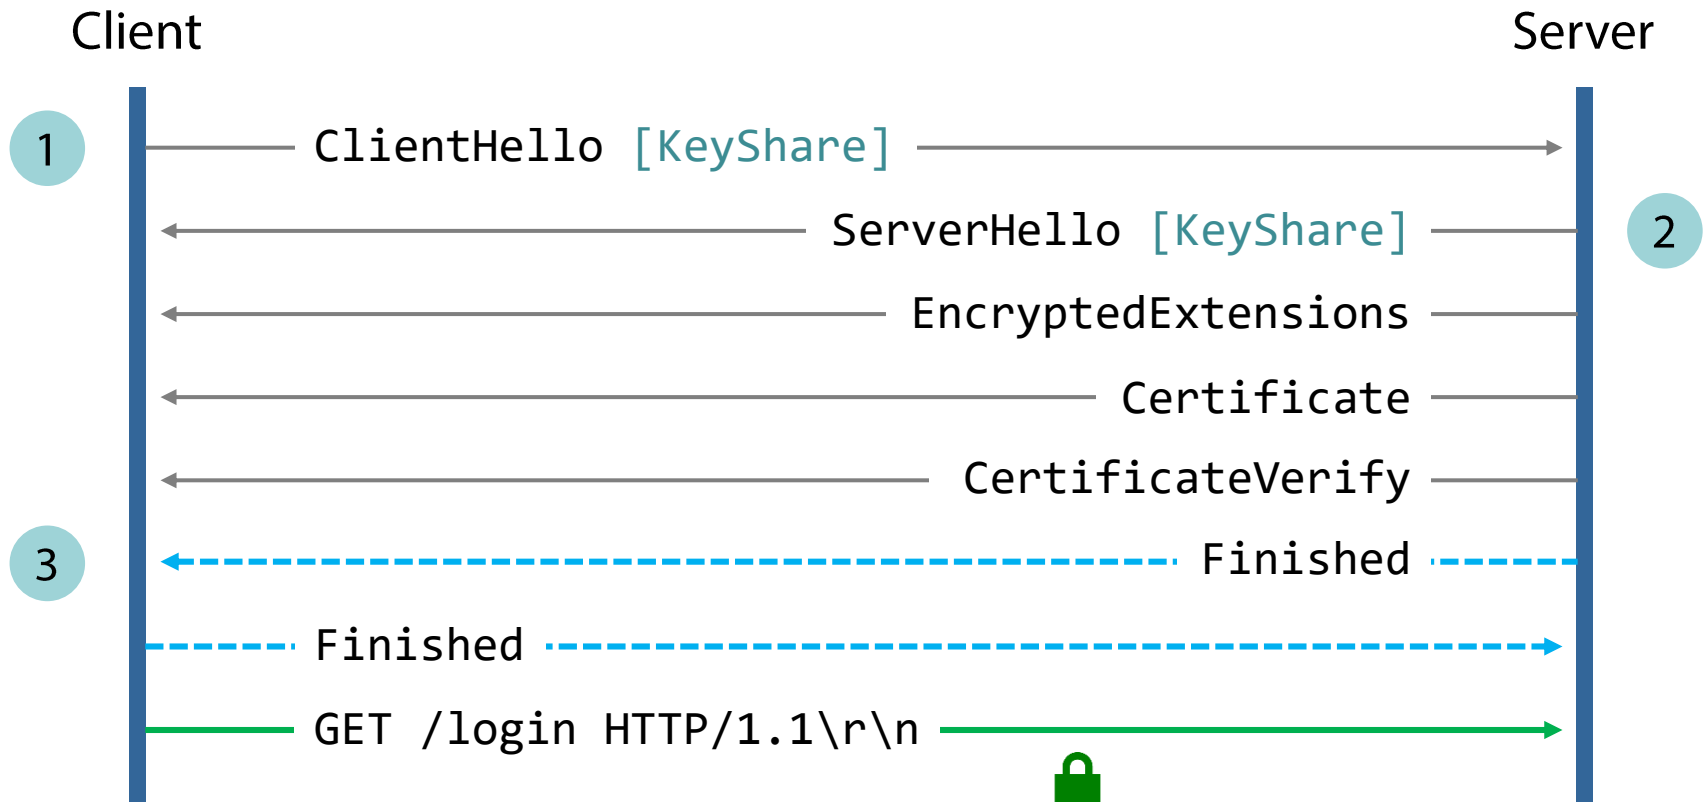

Server assigns and sends a unique session ID as part of ServerHello

In future connections, the client sends the session ID to resume the session

Alternative: *session tickets* (all state is kept at the client)

# TLS 1.3 Handshake (Ephemeral DH)

Latest draft supports even zero-RTT handshakes

Clients include encrypted data in the initial handshake messages  
Based on configuration identifier previously sent by the server

# Server (and Client) Authentication

After handshake completion, the client knows it can “trust” the information in the server’s certificate

Assuming it trusts the issuing CA

SSL/TLS certs are based on the X.509 PKI standard

How is the certificate associated with the server?

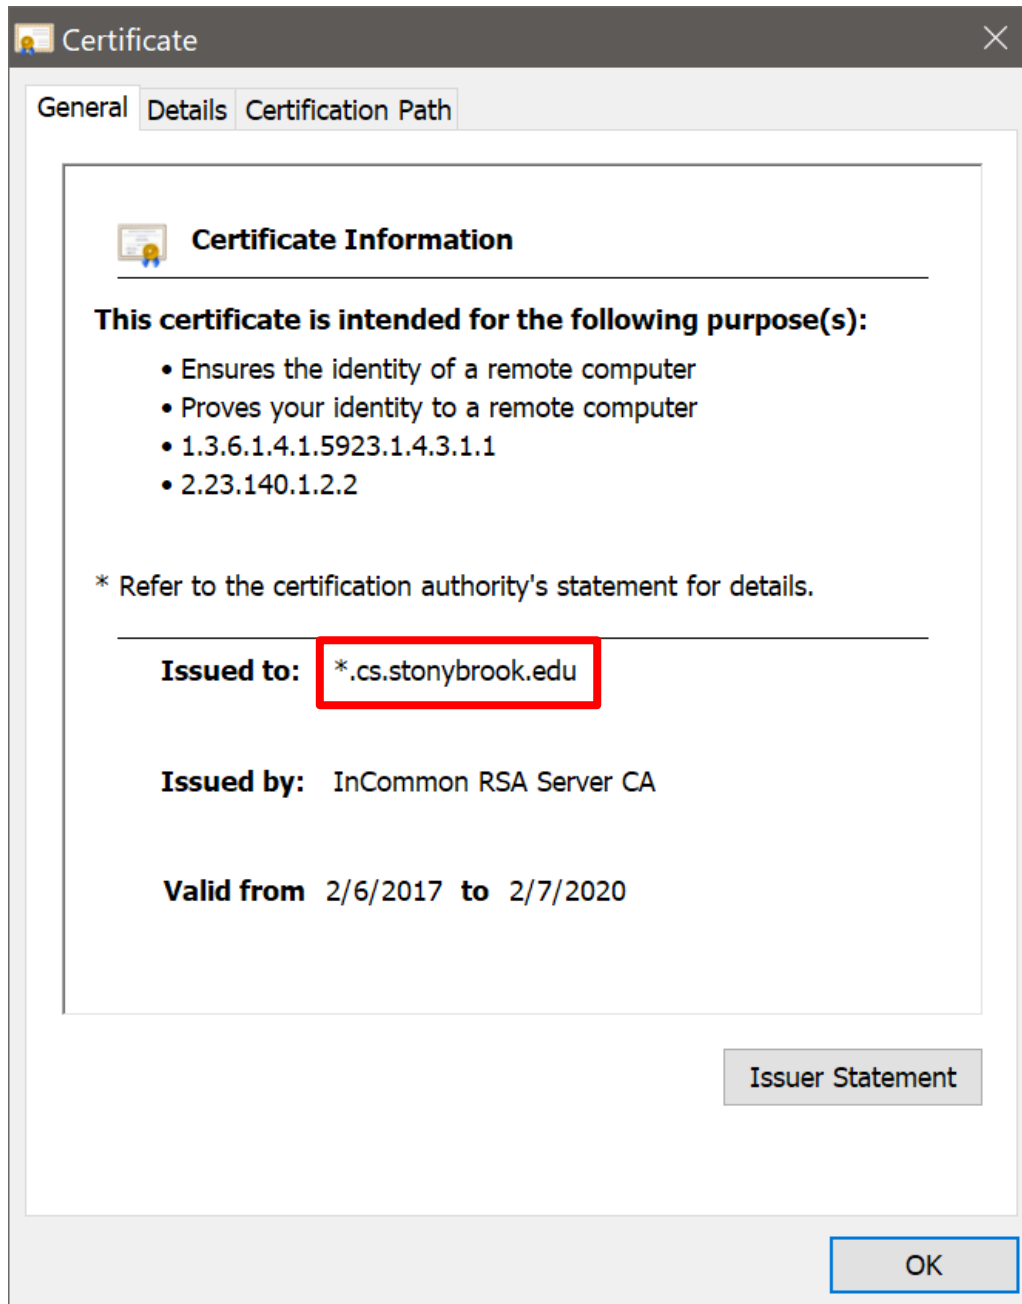

*Common Name (CN): server’s hostname*

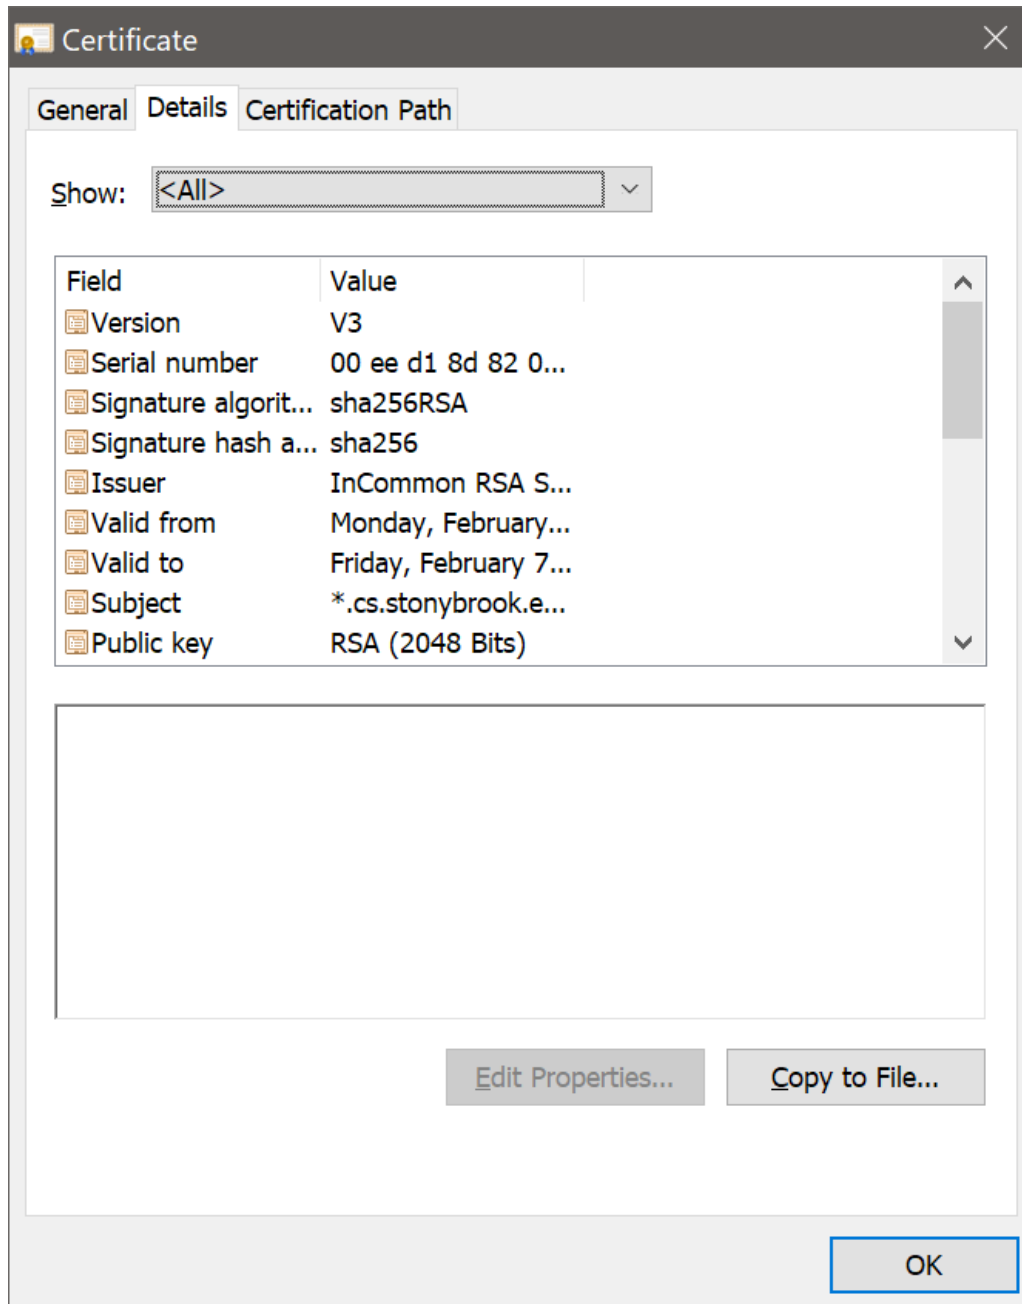

Same process is supported for authenticating clients

Highly-secure web services, some VPN services, ...

Not used often in practice

Common alternative: username + password over TLS connection

# Certificate Chains

Trust anchors: systems are pre-configured with ~200 trusted root certificates

System/public store: used by OS, browsers, ...

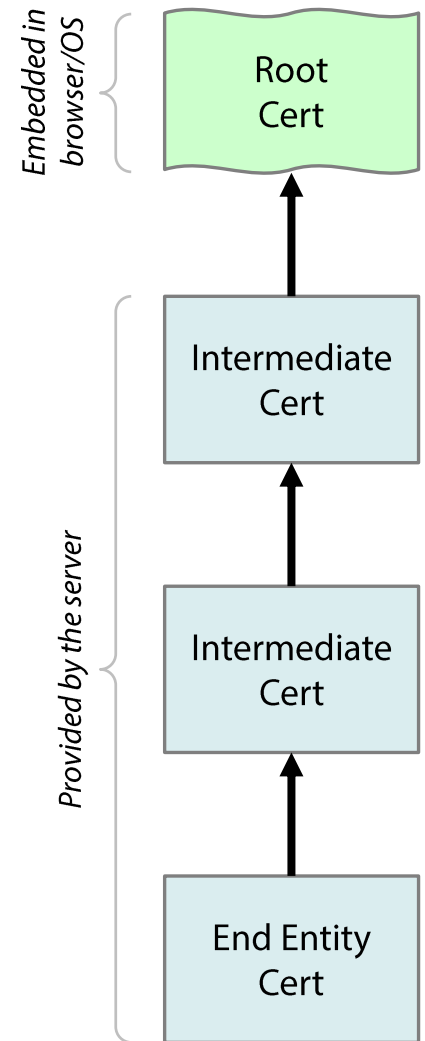

More can be added in the local/private cert store: vendor-specific certs, MitM certs for content inspection filters/AVs, ...

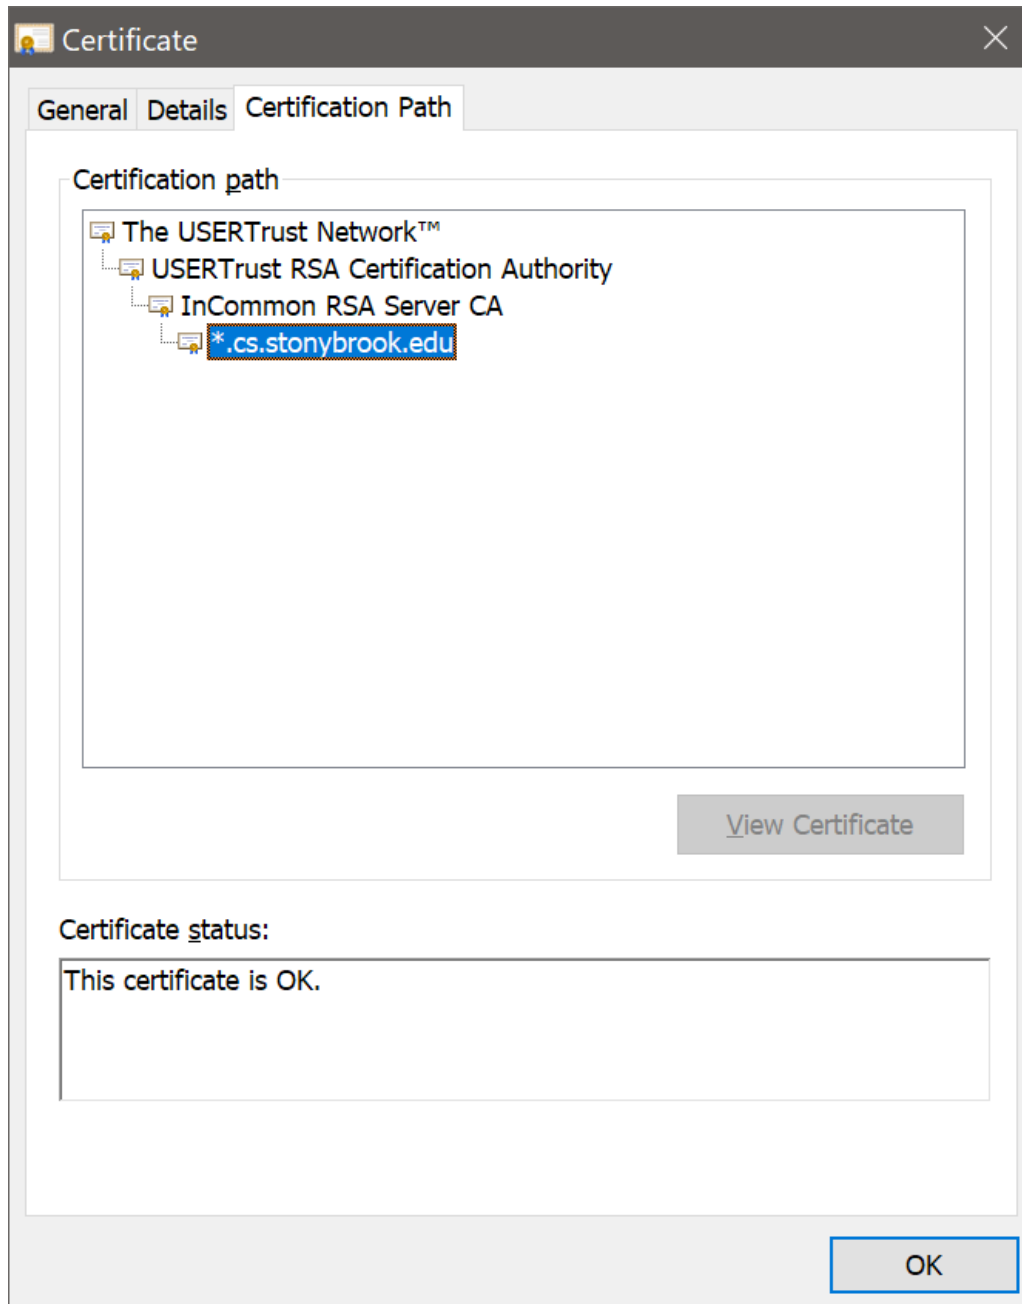

Server provides a *chain* of certificates

A certificate from an intermediate CA is trusted if there is a valid chain of trust all the way back to a trusted root CA

Any certificate authority can issue and sign certificates for any subject

The system is only as secure as the weakest certificate authority...

# HTTPS

## Most common use of SSL/TLS

More than half of web traffic is now encrypted

## Crypto is expensive, needs more CPU cycles

**Not** a big deal these days (native hardware support)

## Mixed content: Ad networks, mashups, ...

**Stop** using them! ...easier said than done (lost revenue, increased development time)

Incentives: Google rewards HTTPS sites with higher ranking

## Virtual Hosting: initially incompatible

**Not** anymore: solved as of TLS 1.1 through the *Server Name Indication (SNI)* extension → what about IE6/WinXP users?

## Needs expertise and certs cost \$\$\$\$

**Not** anymore: letsencrypt.org

# HTTPS Encryption in Chrome

# Browser Security Indicators

Convey information about the security of a page

Locks, shields, keys, green bars...

*"This page was fetched using SSL"*

 Secure | <https://>

Page content was not viewed or altered by a network adversary  
Certificate is valid (e.g. not expired), issued by a CA trusted by the browser, and the subject name matches the URL's domain

*"This page uses an invalid certificate"*

 Not secure | <https://>

*"Parts of the page are not encrypted"*

 <https://>

*"The legal entity operating this web site is known"*

Extended Validation (EV) certificates

 Square, Inc. [US] | <https://square.com>

# Mixed Content Warning

	Chrome 45	Chrome 46
Secure HTTPS		
HTTP		
HTTPS with minor errors		
Broken HTTPS		

} Basically the same in terms of security

Fewer security states for users to remember  
Reflects better the security state of the page  
**Non-HTTPS traffic is a vulnerability!**  
MitM/MotS attacks on the HTTP part are trivial...

# Marking HTTP as Non-Secure

Phase 1: page is marked "Not Secure" when

The page *contains a password field*

The user *interacts with a credit card field*

Treatment of HTTP pages with password or credit card form fields:

Current (Chrome 53)	 login.example.com
Jan. 2017 (Chrome 56)	 Not secure   login.example.com

# Marking HTTP as Non-Secure

## Phase 2: page is marked "Not Secure" when

The page *contains a password field*

The user *interacts with any input field*

The user is browsing in Chrome *incognito mode*

	Treatment of HTTP pages outside Incognito mode:	Treatment of HTTP pages in Chrome Incognito mode:
Current (Chrome 58)	 example.com	 example.com
Oct. 2017 (Chrome 62) at page load	 example.com	 Not secure   example.com
Oct. 2017 (Chrome 62) when entering data	 Not secure   example.com	 Not secure   example.com

# Marking HTTP as Non-Secure

In the future: all HTTP pages are marked “Not Secure”

Eventual treatment of all  
HTTP pages in Chrome:

⚠ Not secure | example.com

# SSL stripping

Browsing sessions often start with a plain HTTP page

Web sites switch to HTTPS only for login or checkout

Example: Facebook in 2010 (optional full HTTPS in 2011, on by default in 2013)

Users type addresses without specifying "https://"

Browser connects over HTTP → site may redirect to HTTPS

SSLstrip [Moxie Marlinspike, Black Hat DC 2009]

MitM attack to prevent redirection to HTTPS

Watch for **HTTPS** redirects and links, and map them to **HTTP** links

...or homoglyph-similar *valid* HTTPS links:

`https://www.bank.com.attacker.com`

# SSL stripping

Location: **http://...**  
<a href="**http://...**">  
<form action="**http://...**">

Location: **https://...**  
<a href="**https://...**">  
<form action="**https://...**">

*Missing lock icon, but who is going to notice?*

# HSTS (HTTP Strict Transport Security)

## Defense against SSL stripping and other issues

Convert any insecure links (**http://**) into secure links (**https://**) *before* accessing a resource

Treat all errors (e.g., invalid certificate, mixed content) as fatal: do not allow users to access the web application

A server implements an HSTS policy by supplying an extra HTTP header

**Strict-Transport-Security: max-age=31536000**

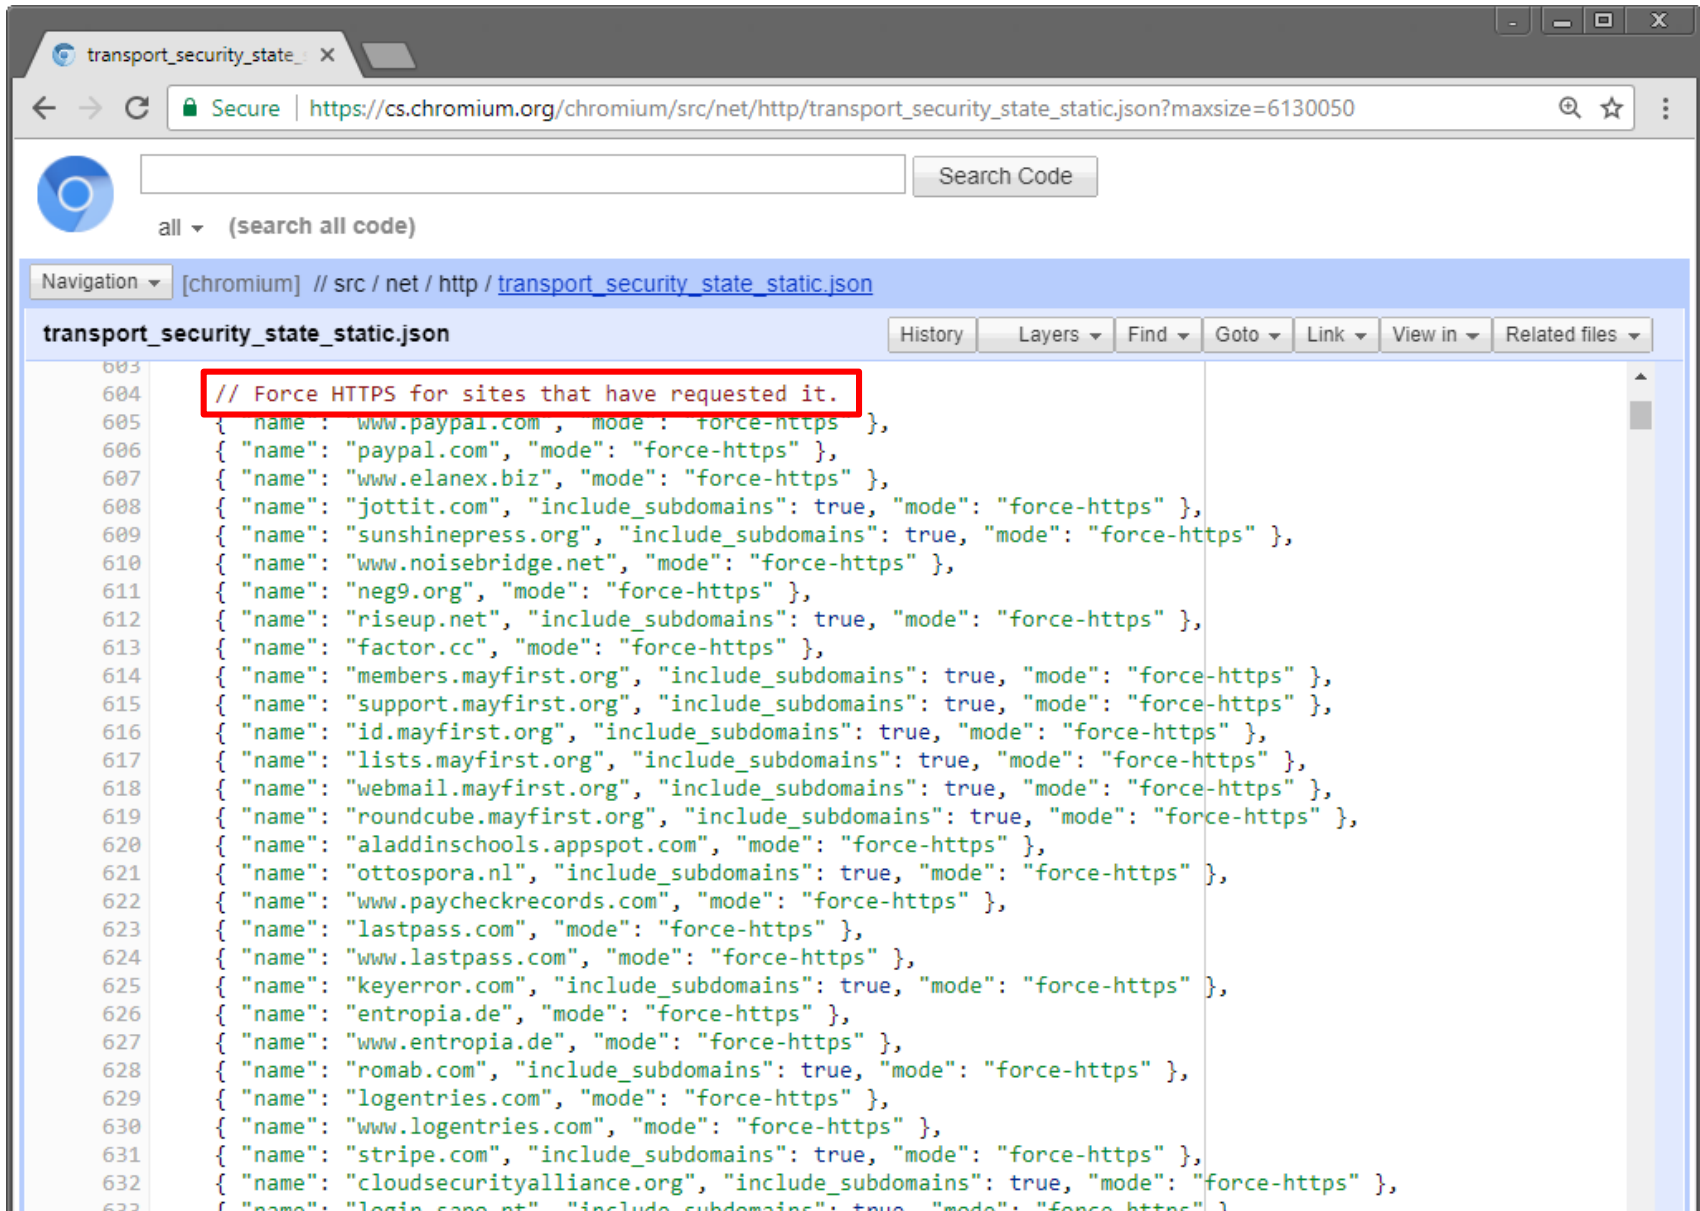

*“Use only HTTPS for future requests to this domain for the next year”*

An instance of *trust on first use (TOFU)*

The initial request *remains unprotected* if sent over HTTP

HSTS preloading: browser comes with a list of known HSTS sites

# HSTS Preloading

The screenshot shows a web browser window displaying the Chromium source code for the HSTS preloading list. The URL in the address bar is `https://cs.chromium.org/chromium/src/net/http/transport_security_state_static.json?maxsize=6130050`. The code is displayed in a monospaced font, and the line `// Force HTTPS for sites that have requested it.` is highlighted with a red box. The code lists various domains and their HSTS modes, such as `force-https` and `force-https` with `include_subdomains: true`.

```
603
604 // Force HTTPS for sites that have requested it.
605 { "name": "www.paypal.com", "mode": "force-https" },
606 { "name": "paypal.com", "mode": "force-https" },

633 { "name": "login.sage.nt", "include_subdomains": true, "mode": "force-https" }
```

# MitM is Still Possible...

## Rogue certificates

Most governments have a trusted root CA planted in our systems  
Attackers may break into CAs and forge certificates

## Pre-planted/generated certificates

Default static keys: Lenovo, Dell, anti-malware software, ...

Low entropy during key generation: repeated or factorable keys

## Self-signed certificates

If desperate... will trigger browser warning

## Exploitation of certificate validation flaws

Programming errors while checking date, hostname, ...

## StartSSL suspends services after security breach

StartSSL has suspended issuance of digital certificates and related services following a security breach on 15 June. A trademark of Eddy Nigg's StartCom, the StartSSL certificate authority is well known for offering free domain validated SSL certificates, but also sells organisation and extended validation certificates.

More than 25 thousand websites in Netcraft's SSL survey use certificates issued by StartSSL. These are recognised by Internet Explorer, Firefox, Chrome and other mainstream browsers.

StartSSL is not alone in offering free certificates. AffirmTrust recently trumped StartSSL's one-year

certificates with its own offer of free three-year domain validated SSL certificates. Coincidentally, AffirmTrust announced its launch [on the same day](#) as the StartSSL security breach.

StartSSL is also not the only certificate authority to come under attack this year. In March, Comodo came [under attack](#) through three of its resellers. By compromising a [GlobalTrust](#) website, the so-called *ComodoHacker* managed to fraudulently issue several valid certificates, including ones for the login pages of Yahoo and Skype. These certificates were subsequently revoked and browser software was updated to explicitly

# Trustwave to escape 'death penalty' for SSL skeleton key

## Moz likely to spare certificate-confession biz same fate as DigiNotar

14 Feb 2012 at 09:28, John Leyden

12

10

**Analysis** Trustwave's admission that it issued a digital "skeleton key" that allowed an unnamed private biz to spy on SSL-encrypted connections within its corporate network has sparked a fiery debate about trust on the internet.

Trustwave, an SSL certificate authority, confessed to supplying a subordinate root certificate as part of an information security product that allowed a customer to monitor employees' web communications - even if the staffers relied on HTTPS. Trustwave said the man-in-the-middle (MitM) gear was designed both to be tamper-proof and to work only within its unnamed client's compound. Despite these precautions, Trustwave now admits that the whole approach was misconceived and would not be repeated. In addition, it revoked the offending certificate.

Trustwave came clean without the need for pressure beforehand. Even so its action have split security experts and prompted calls on Mozilla's Bugzilla security list to remove the Trustwave root certificate

# Self-signed Certificate Warning: One click away...

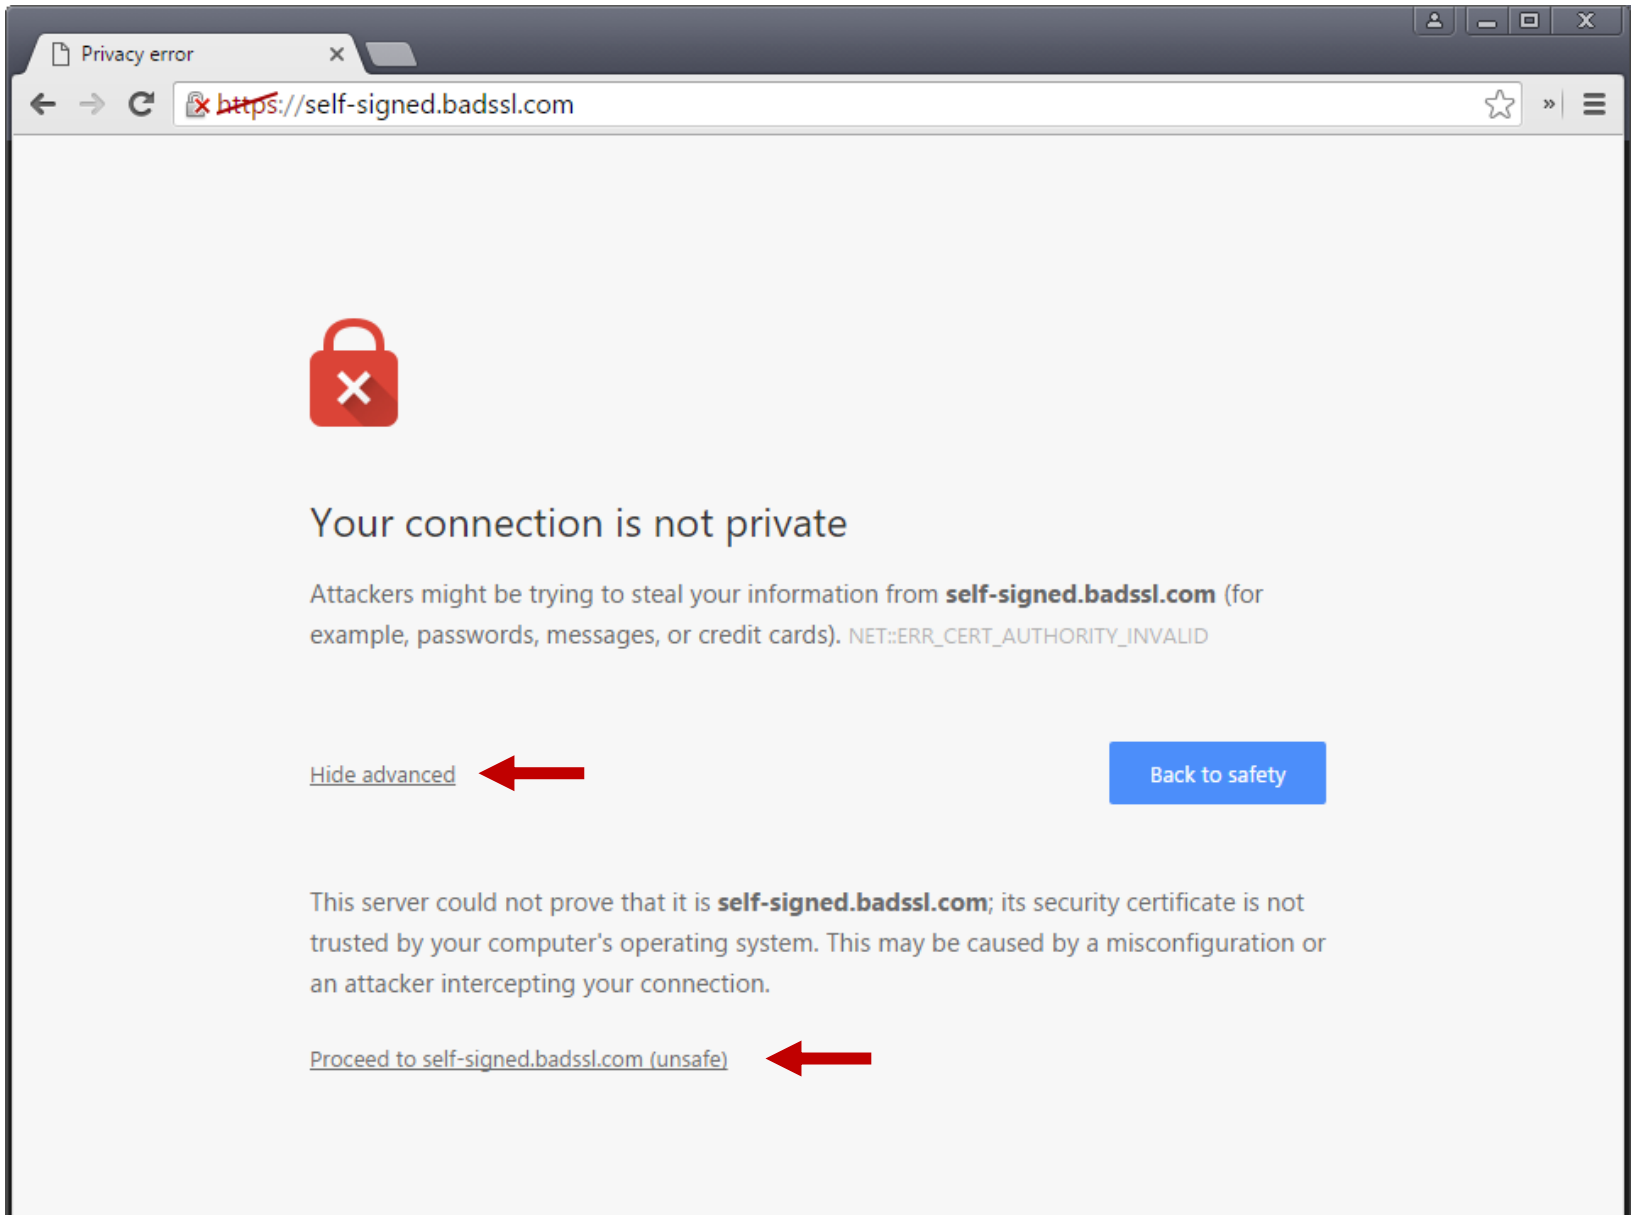

# Self-signed Certificate Warning: Two clicks away...

# Self-signed Certificate Warning: Two clicks away...

The screenshot shows a browser window with a tab titled "Privacy error". The address bar displays a red lock icon and the URL <https://self-signed.badssl.com>. The main content area features a red padlock icon with a white "X" inside. Below the icon, the text reads "Your connection is not private". A warning message follows: "Attackers might be trying to steal your information from **self-signed.badssl.com** (for example, passwords, messages, or credit cards). NET::ERR\_CERT\_AUTHORITY\_INVALID". At the bottom of the warning, there are two links: "[Hide advanced](#)" and a blue button labeled "Back to safety". A red arrow points to the "Hide advanced" link. Below this, a paragraph explains: "This server could not prove that it is **self-signed.badssl.com**; its security certificate is not trusted by your computer's operating system. This may be caused by a misconfiguration or an attacker intercepting your connection." At the bottom of the page, there is a link "[Proceed to self-signed.badssl.com \(unsafe\)](#)" with a red arrow pointing to it.

# GOTO FAIL

## iOS 7.0.6 signature verification error

Legitimate-looking TLS certificates with a mismatched private keys were unconditionally accepted...

```
if ((err = SSLHashSHA1.update(&hashCtx, &serverRandom)) != 0)
    goto fail;
if ((err = SSLHashSHA1.update(&hashCtx, &signedParams)) != 0)
    goto fail;
goto fail; ← ?!?!?!?
if ((err = SSLHashSHA1.final(&hashCtx, &hashOut)) != 0)
    goto fail; ←
...
Check never executed
fail:
    SSLFreeBuffer(&signedHashes);
    SSLFreeBuffer(&hashCtx);
    return err;
```

## HPKP (HTTP Public Key Pinning)

Prevent *certificate forgery*: strong form of web site authentication

Browser knows the *valid* public keys of a particular website

If a seemingly valid chain does not include at least one known pinned key, cert is rejected → not issued according to the site's expectations

Doesn't apply for *private* root certificates

Would break preconfigured proxies, anti-malware, content filters, ...

Many incidents involving rogue certificates were discovered after browsers started rolling out pinning

Similar deployment as HSTS

TOFU: HTTP response header

Built-in pins in browsers

***Must be used very carefully – things can go wrong***

HPKP suicide: site can be bricked if keys are lost/stolen

RansomPKP: compromise the server and push a malicious HPKP key

## Enhancing digital certificate security

January 3, 2013

Posted by Adam Langley, Software Engineer

Late on December 24, **Chrome detected and blocked an unauthorized digital certificate for the "\*.google.com" domain.** We investigated immediately and found the certificate was issued by an **intermediate certificate authority (CA)** linking back to TURKTRUST, a Turkish certificate authority. Intermediate CA certificates carry the full authority of the CA, so anyone who has one can use it to create a certificate for any website they wish to impersonate.

In response, we updated Chrome's certificate revocation metadata on

## Intent To Deprecate And Remove: Public Key Pinning

31 posts by 14 authors

Chris Palmer

Oct 27

### Primary eng (and PM) emails

[palmer@chromium.org](mailto:palmer@chromium.org), [rsleeve@chromium.org](mailto:rsleeve@chromium.org), [estark@chromium.org](mailto:estark@chromium.org), [agl@chromium.org](mailto:agl@chromium.org)

### Summary

Deprecate support for public key pinning (PKP) in Chrome, and then remove it entirely.

This will first remove support for [HTTP-based PKP](#) ("dynamic pins"), in which the user-agent learns of pin-sets for hosts by HTTP headers. We would like to do this in Chrome 67, which is estimated to be released to Stable on 29 May 2018.

Finally, remove support for built-in PKP ("static pins") at a point in the future when Chrome requires Certificate Transparency for all publicly-trusted certificates (not just newly-issued publicly-trusted certificates). (We don't yet know when this will be.)

### Motivation

PKP offers a way to defend against certificate misissuance, by providing a Web-exposed mechanism (HPKP) for sites to limit the set of certificate authorities (CAs) that can issue for their domain. However, this exposes as part of the Open Web Platform considerations that are external to it: specifically, the choice and selection of CAs is a product-level security decision made by browsers or by OS vendors, and the choice and use of sub-CAs, cross-signing, and other aspects of the PKI hierarchy are made independently by CAs.

As a consequence, site operators face difficulties selecting a reliable set of keys to pin to, and adoption of PKP has remained low. When site operators' expectations don't match the reality of trust anchors on real world client machines, users suffer. Unexpected or spurious pinning errors can result in error fatigue rather than user safety.

Concretely:

# Certificate Revocation

Mechanism to allow revocation of compromised or no longer needed certificates

## Certificate revocation list (CRL)

Signed list of all serial numbers belonging to revoked certificates that have not yet expired

Main problem: lists tend to be large, making real-time lookups slow

Can the attacker block connectivity to the status server?

## Online Certificate Status Protocol (OCSP)

Obtain the revocation status of a *single* certificate → faster

But performance and privacy issues still remain

**OCSP stapling:** server embeds OCSP response directly into the TLS handshake

# Certificate Transparency

## Public monitoring and auditing of certificates

Identify mistakenly or maliciously issued certs and rogue CAs

### *Certificate logs*

Network services maintaining cryptographically assured, publicly auditable, append-only records of certificates

### *Monitors*

Periodically contact all log servers and watch for suspicious certificates

### *Auditors*

Verify that logs are behaving correctly and are cryptographically consistent

Check that a particular certificate appears in a log
