

CSE 332

INTRODUCTION TO VISUALIZATION

VISUAL PERCEPTION AND COGNITION

KLAUS MUELLER

COMPUTER SCIENCE DEPARTMENT
STONY BROOK UNIVERSITY

Lecture	Topic	Projects
1	Intro, schedule, and logistics	
2	Applications of visual analytics, data types	
3	Data sources and preparation	Project 1 out
4	Data reduction, similarity & distance, data augmentation	
5	Dimension reduction	
6	Introduction to D3	
7	Visual communication using infographics	
8	Visual perception and cognition	Project 2 out
9	Visual design and aesthetic	
10	Visual analytics tasks and cluster analysis	
11	High-dimensional data, dimensionality reduction	
12	Principal component analysis (PCA)	
13	Visualization of spatial data: volume visualization intro	Project 3 out
14	Introduction to GPU programming	
15	Visualization of spatial data: raycasting, transfer functions	
16	Illumination and isosurface rendering	
17	Midterm	
18	Scientific visualization	
19	Non-photorealistic and illustrative rendering	Project 4 out
20	Midterm discussion	
21	Principles of interaction	
22	Visual analytics and the visual sense making process	
23	Visualization of graphs and hierarchies	
24	Visualization of time-varying and streaming data	Project 5 out
25	Maps	
26	Memorable visualizations, visual embellishments	
27	Evaluation and user studies	
28	Narrative visualization, storytelling, data journalism, XAI	

THE HUMAN EYE

The discs of rods hold rhodopsin and the discs of cones hold photopsin. Both of these photoreceptor proteins are special molecules that change shape when activated by light. This shape change allows the proteins to activate a second special protein molecule that then starts causing other changes involved in sending a visual signal. For the signal to be sent through the cell, charged molecules called ions are let in and out of the cell in an action potential.

RETINAL DISTRIBUTION OF RODS AND CONES

What can you observe here?

- color (cones) in the center
- grey (rods) outside, too
- more grey
- more green
- blind spot

SUCCESSIVE CONTRAST

Focus on the black circle for a few seconds, then switch to one of the white fields.

What do you see?

SCALED UP TO AN OPTICAL ILLUSION

EXPLANATION

While the retina can perceive a high range of intensities, it cannot handle all simultaneously

- at any given time, each region adapts to a small intensity range determined by the local intensity
- that is why you have to wait a while when you step from a bright into a dark room (say, a dark movie theater from a brightly lit lobby)

RECALL THIS OPTICAL ILLUSION

Follow the instructions:

- 1) Relax and concentrate on the 4 small dots in the middle of the picture for about. 30-40 secs.
- 2) Then, take a look at a wall near you (any smooth, single coloured surface)
- 3) You will see a circle of light developing
- 4) Start blinking your eyes a couple of times and you will see a figure emerging...
- 5) What do you see? Moreover, who do you see?

DYNAMIC RANGE CONTRAST

Local adaption level varies, which changes the relative contrast of the objects in the local scene

Are these two strips the same or different?

SURROUND MATTERS ESPECIALLY FOR COLORS

Compare these three panels

- white background
- saturated background
- non-saturated background

Guidelines:

- use saturated colors sparingly
- they may cause undesired effects
- neutral borders can help

Spectrum of Wavelengths

Spectrum:

The human eye differentiates about 300 hues and 100-150 luminance variations

Perception Curves

Human spectral sensitivity to color

Three cone types (ρ , γ , β) correspond *roughly* to R, G, B.

human color sensitivity curves

color generation by mixing RGB primaries

Perceptual Color Spaces

- Instead of R, G, B primaries it uses X, Y, Z primaries
- Normalizing for luminance and perceptive distance yields the CIE chromaticity diagram (1931)

- Points on the boundary are the pure spectrum colors (from red to blue)
- Note: the purple line (joining blue and red) is not part of the visible spectrum of pure colors
- Interior points represent all visible colors (equidistant colors cause equal perceptive difference)
- Point 'C' is the white-light position

SO, CAN YOU GENERATE ALL VISIBLE COLORS WITH THREE PRIMARIES?

The CIE Chromaticity Diagram

Color gamuts:

- all colors on the line C1-C2 can be generated by mixing proper amounts of C1 and C2
- all colors within the triangle C3-C4-C5 can be generated by mixing amounts of C3, C4, C5
- the triangle defined by the primaries C3, C4, C5 defines the gamut of the monitor

Notice: no triangle can encompass all visible colors in the CIE → modern monitors are unable to display all visible colors

Complementary colors:

- C1, C2 are complementary when the gamut line C1-C2 goes through the white point C
- we can create white light by mixing appropriate amounts of C1 and C2
- also, we can create C1 by subtracting some amount of C2 from white light

Pure color (hue) of a color:

- Extending line C4-C to the border yields the hue of C4

The CIE Chromaticity Diagram

Complementary colors:

- C1, C2 are complementary when the gamut line C1-C2 goes through the white point C
- we can create white light by mixing appropriate amounts of C1 and C2
- also, we can create C1 by subtracting some amount of C2 from white light

Pure color (hue) of a color:

- Extending line C4-C to the border yields the hue of C4

THE MUNSELL PERCEPTUAL COLOR SPACE

The (irregularly shaped) Munsell tree has 3 axes:

- chroma (saturation): distance from the core (values 0-30, with fluorescent colors having the maximum 30)
- value (brightness): vertical axis (0– 10 (white))
- hue: 10 principal hues (R, YR, Y, GY, G, BG, B, PB, P, RP)

NON-PERCEPTUAL COLOR SPACES

How to convert from RGB to HSV?

CONTRAST REVISITED

Difference of brightness in adjacent regions of the image

- grey-level (luminance) contrast
- color contrast

C	H	V	O	S	N
D	S	Z	N	R	K
N	D	R	H	V	Z
C	S	O	N	K	H
K	N	V	D	S	R
Z	R	D	K	H	O
H	Z	C	V	R	K
S	C	Z	D	V	O

CONTRAST NEEDS BRIGHTNESS DIFF.

Munsell tree – unwrapped

- ignore the circles
- look at what heights the longest rows are

color

same image in grey-scale (brightness only)

CHROMATIC ABERRATION

Different wavelengths of light are focused at different distances within the eye

- short-wavelength blue light is refracted more than long-wavelength red light
- focusing on a red patch, an adjacent blue patch will be significantly out of focus
- the human eye has no correction for chromatic aberration

Most people see red
Closer than blue

This is really painful

This is better

WIRING: THE VISUAL PATHWAYS

PROCESSING UNIT: THE VISUAL CORTEX

Visual cortex breaks input up into different aspects:

- color, shape, motion, depth

Pre-Attentive Processing

If you want it or not: some features are always detected

And fast – within 200 ms or less

Pre-Attentive Processing

Why is it so fast?

Well, because 50% of the brain is dedicated to vision

Vision is a MASSIVELY parallel processor dedicated to

- detect
- analyze
- recognize
- reason with

visual input

Pre-Attentive Processing

Sensitivity to differences in:

- color, orientation, size, shape, motion, shading, 3D depth, ...

Pre-Attentive Processing

But there are limits: conjunctions don't work well

quick: find the blue circle

Pre-Attentive Processing

Some features/cues are stronger than others:

Look at the chart and say the COLOUR not the word

YELLOW	BLUE	ORANGE
BLACK	RED	GREEN
PURPLE	YELLOW	RED
ORANGE	GREEN	BLACK
BLUE	RED	PURPLE
GREEN	BLUE	ORANGE

Left – Right Conflict

Your right brain tries to say the colour but your left brain insists on reading the word.

Pre-Attentive Processing

Now try this (left brain takes a break)

Pre-Attentive Processing

Words are patterns, which form strong pre-attentive feature

- this would have been different if this had been done in Arabic

There are limits, however

- let's see the next experiment

Pre-Attentive Processing

Reading 1

According to a research at an English university, it doesn't matter in what order the letters in a word are, the only important thing is that first and last letter is at the right place. The rest can be a total mess and you can still read it without problem. This is because we do not read every letter by itself but the word as a whole

Pre-Attentive Processing

Now, is this true? Read on....

Pre-Attentive Processing

Pre-Attentive Processing

Reading 2

According to card carrying linguistics professionals at an unnamed, university in British Columbia, and contrary to the dubious claims of the uncited research, a slpmie, macinahcel ioisrevnn of ianretnl cretcarahs araepps sneiciffut to csufnoe the eadyrevy oekoolnr

Pre-Attentive Processing

Reading 2

According to card carrying linguistics professionals at an unnamed, university in British Columbia, and contrary to the dubious claims of the uncited research, a simple, mechanical inversion of internal characters appears sufficient to confuse the everyday onlooker

What To Learn From This

The human visual system (HSV) tolerates (visual) noise very well

- it can read the randomly garbled text very well
- machines (equipped with computer vision) are poor at this

Humans have only limited computational capacity

- hard to execute a fixed rule to decipher text
- especially once the text gets longer (7 ± 2 rule of working memory)
- this is where computers excel

The fact that computers deal poorly with noisy patterns is exploited in CAPTCHA

- **CAPTCHA: Completely Automated Public Turing Test to tell Computers and Humans Apart**
- used to ensure that an actual human is interacting with a system
- some examples:
 - creating a new gmail or yahoo account (prevent spammer accounts)
 - submitting files, data, email

CAPTCHA

CAPTCHA: noisy and vastly distorted patterns that are difficult to recognize by machines

CAPTCHA

But computer vision algorithms have become more sophisticated at CAPTCHA *character* recognition

- the latest approach is *object* recognition

Organization of the Human Brain

- LGN: left lateral geniculate nucleus of the thalamus
- V1: primary visual cortex
 - a quarter-sized area in the back of the head (the first cortical stage for most visual processing)
- Higher-level areas dedicated to spatial reasoning, associative object recognition, etc.

Measuring Orientation Maps

- Use optical imaging techniques to measure orientation preferences for a large number of neurons
 - remove part of the skull of a laboratory animal, exposing the surface of the visual cortex
 - present visual patterns to the eyes
 - a video camera records either light absorbed by the cortex or light given off by fluorescent chemicals applied to it
 - compare measurements between different stimulus conditions (orientations, temporal, etc)
- See *Topographica* software by Miikkulainen, Bednar, et. al. at University of Texas, Austin
 - java demos available at: <http://www.cs.utexas.edu/users/jbednar/demos.html>

Organization and Sensitivity of the Visual Cortex

Organization and Sensitivity of the Visual Cortex

- Brain is sensitive to edges (contrast in intensity and color), pre-attentive
- Some more example obtained using *Topographica*:

Organization and Sensitivity of the Visual Cortex

diagonal line

circle

Pre-Attentive Cues With Textures

- A visual texture represents that visual sensation that allows us to pre-attentively differentiate two adjacent, possibly structured parts in our visual field without eye movement
 - visual textures include micro-structures, patterns, profiles, etc.
 - to identify textures, an observations of about 160-200 ms is sufficient (cognitively controlled processes require about 300-400 ms)
- Classification of textures is based on
 - coarseness, contrast, directionality, line-likeness, regularity, roughness
- Textures improve perception of position and orientation
- Texture communicate information about the 3D structure regardless of their coloring

Pre-Attentive Cues With Textures

- Same surface with and without texture

- Textures that do not include information are to be avoided in visualization
 - recall Tufte's aesthetic principle that irrelevant decoration (= chart junk) should be avoided
- Subtle textures for 3D visualizations, however, can be important elements of visual design
 - see above

Texture Perception

- *Textons*

- fundamental micro-structures in generic natural images
- basic elements in pre-attentive visual perception

- Textons can be classified into three general categories:

1. elongated blobs (line segments, rectangles, ellipses) with specific properties such as hue, orientation, and width, at different level of scales
2. terminators (end of line segments)
3. crossings of line segments

- Recall the sensitivity of the neurons in V1

objects

their textons

Gabor primitives

Relation to Symbol and Texture Design

- When designing textures to indicate different regions of a visualization, make sure that the textures are as different as possible
- The same rules apply when designing symbol sets
- Example: A tactical map may require the following symbols:
 - aircraft targets
 - tank targets
 - building targets
 - infantry position targets
- Each of these target types can be classified as *friendly* or *hostile*
- Targets exist whose presence is suspected but not confirmed (this uncertainty must be encoded)
- Set of symbols designed to represent different classes of objects
 - symbols should be as distinct as possible with respect to their pre-attentive processing
 - recall: military reconnaissance must occur FAST!

Information Display in 3D: Depth Cues

- 3D display should provide *depth cues*
- Linear perspective:
 - more distant objects become smaller in the image
 - > can indicate focus, importance, or ordering
 - elements of a uniform texture become smaller with distance --> can give shape cues

- Shadows:
 - show the relative height of objects above a surface
 - provide strong depth cues for objects in motion
 - can be semi-realistic and still work as a depth cue
- Occlusion:
 - very powerful depth cue

Information Display in 3D: Depth Cues

- Shading:

- shape cues from shading (*shape-from-shading*)

diffuse

+ specular

+ shadows

shape from shading
(hole vs. hill)

specular can reveal fine detail

assume single light source
having more than one light
source can lead to confusion

Information Display in 3D: Depth Cues

- Other depth cues:
 - depth of focus
 - motion parallax (structure from motion) --> how objects relate under motion
 - stereoscopic depth (binocular displays)
- For fine-scale judgement, for example, threading a needle:
 - stereo is important, and shadows and occlusion
- For large-scale judgement
 - linear perspective, motion parallax, and perspective are important
 - stereo is not so important

- However, for information visualization displays, one may exploit focus to emphasize importance, despite depth relationships
