

# Testing in Software Development

CSE 114: Introduction to Object-Oriented Programming

Paul Fodor

Stony Brook University

<http://www.cs.stonybrook.edu/~cse114>

# Today's Topics

- Everybody makes mistakes/errors - We must deal with errors in programming
  - Prevention vs Detection
- Testing and debugging
- Unit testing
- Test automation
- Thin interfaces
- Unit Testing with **JUnit**
  - Using **JUnit** in Eclipse
- Exhaustive vs. Sampled Testing
  - Black-box testing
    - Boundary Conditions
  - Glass-box testing
    - Structural Analysis & Path Completeness Table
- Notes on **static import**
- Notes on **assertions**

# Everybody makes mistakes/errors

- We must deal with errors in programming
- Early errors are usually syntax errors
  - The compiler will spot these
- Later errors are logic errors - also known as bugs
  - The compiler cannot help with these
    - Some logical errors have no immediately obvious manifestation
- Prevention vs Detection
  - As developers, we can lessen the likelihood of errors by using software engineering techniques, like encapsulation.
  - We can improve the chances of detection by using software engineering practices, like modularization and documentation.
  - We can develop our detection skills.

# Prevention of errors

- Keep It Simple, Stupid (KISS): Avoid over-engineering. Complex code breeds hidden edge cases.
- Don't Repeat Yourself (DRY): Duplicate code means duplicate bugs. If you find a bug in one place, you have to remember to fix it everywhere else it was pasted.
- Test-Driven Development (TDD): Writing your tests before writing the actual code forces you to think through edge cases, inputs, and outputs ahead of implementation.
- Clear Requirements: Many bugs aren't technical; they are misunderstandings of what the software should do. Behavior-Driven Development (BDD) writes requirements in "Given-When-Then" scenarios to aligns designers/product managers, developers, and QA testers before code is even written.
- Avoid "Magic Numbers": use named constants instead of hardcoded strings or numbers.

# Prevention of errors through Testing and Debugging

- *Testing* searches for the presence of errors.
- *Debugging* searches for the source of errors.
- Testing techniques:
  - Unit testing
  - Test automation
- Debugging techniques (covered at the beginning of the semester):
  - Manual walkthroughs
  - Print statements
  - Debuggers

# Unit testing

- Each unit of an application may be tested.
  - Methods, classes, and modules (packages in Java).
- Can (and should) be done during development.
  - Finding and fixing errors early
    - Lowers development costs (e.g. programmer time) in long term
  - A test suite is built up.
- For each unit, understand what the unit should do (its contract)
  - You will be looking for violations
    - Use positive tests and negative tests
    - Test boundaries: Zero, One, Full.
      - Example: for sorting, try an empty array, an array of 1 element, an array with lots of elements.

# Test automation

- Testing is repetitive (rerun after each update or daily updates)
- *Regression testing* involves re-running tests.
  - Human analysis of the results may be still required.
  - Fuller automation: intervention only required if a failure is reported.
    - If tests fail, explore the changes/updates/commits to debug/find the introduction of the error.

# Thin interfaces

- *Thin interfaces:*
  - Large applications often consist of different modules, so that different teams can work on them
  - The interface between modules must be clearly specified and Tested. Reducing Cognitive Load & Clear Specifications.
  - Each module does not need to know implementation details of the other. Information Hiding (Encapsulation).

# Unit Testing with JUnit

- *JUnit* is the de facto framework for testing Java programs
- JUnit is a third-party open source library
- It contains a tool called *test runner*, which is used to run test programs.

# Unit Testing with JUnit

- Suppose you have a class named A.
- By convention, if the class to be tested is named A, the test class should be named ATest.
- This test class, called a *test class*, contains the methods you write for testing class A.
- The test runner executes ATest to generate a test report

# Using JUnit in Eclipse

- Eclipse come with JUnit (including JUnit 5 and JUnit 6) **pre-bundled**.
  - **Create a Test Class:** In your Package Explorer, right-click on your project or source folder and select **New > JUnit Test Case**.
  - **Select the JUnit Version:** In the wizard that pops up, you will see radio buttons to select the JUnit version on the top - select **New JUnit Jupiter test** for JUnit 5/6
  - In the next screen, select a class that you want to test
  - In the next screen, select "**Add JUnit 5 to build path**". Eclipse will instantly attach the required libraries to your project.
  - **Run Your Tests:** Right-click your test file, Select **Run As > JUnit Test**
    - The JUnit View tab will open up, showing you if your tests pass!

```

public class A {
    public int add(int a, int b) {
        return a + b;
    }
}

import static org.junit.jupiter.api.Assertions.*;
import org.junit.jupiter.api.DisplayName;
import org.junit.jupiter.api.Test;
class TestA {
    @Test
    @DisplayName("Testing standard addition of two positive integers")
    void testAddPositiveNumbers() {
        // 1. Arrange (Set up your object and data)
        A calculator = new A();
        // 2. Act (Execute the method under test)
        int result = calculator.add(5, 3);
        // 3. Assert (Verify the result matches expectations)
        // assertEquals(expected, actual, optional_failure_message)
        assertEquals(8, result, "5 + 3 should equal 8");
    }
    @Test
    @DisplayName("Testing addition with a negative integer")
    void testAddNegativeNumbers() {
        A calculator = new A();
        assertEquals(-2, calculator.add(3, -5), "3 + (-5) should equal -2");
        // you can add more tests
        assertEquals(0, calculator.add(0, 0), "0 + 0 should equal 0");
    }
}

```

# Arrange-Act-Assert (AAA) pattern

- Part of Test-Driven Development (TDD)
  - Arrange is the setup phase. Here, you initialize the objects, prepare the data, and configure the environment needed for your test.
    - Goal: Put the system into the exact state required for the test to run.
    - Examples: Creating instances of classes or defining input variables.
  - Act is the execution phase. You invoke the specific method or action that you want to test.
  - Assert is the verification phase. You check the outcome of the action against your expectations by comparing the returned value to an expected value, checking if an object's state changed, or verifying that a specific side effect occurred (like a file being written).

# Exhaustive vs. Sampled Testing

- How do we generate test cases?
  - Exhaustive
    - Consider all possible combinations of inputs
    - Often infeasible
  - Sampled
    - A small but representative subset of all input combinations
      - Black-box testing - Test cases generated from program specifications and not dependent on the implementation
      - Glass-box testing - Test cases generated from program's code

# Black-box testing

- Test cases should cover all paths (not all cases) through the specification, including exceptions.
- Test cases based on program's specification, not on its implementation.
- It is the best place to start when attempting to test a program thoroughly
- Test cases are not affected by:
  - Invalid assumptions made by the programmer
  - Implementation changes
    - Use same test cases even after program structures has changed
- Test cases can be generated by an “independent” agent, unfamiliar with the implementation.

# Boundary Conditions

- A boundary condition is an input that is “one away” from producing a different behavior in the program code
- Such checks catch 2 common types of errors:
  - Logical errors, in which a path to handle a special case presented by a boundary condition is omitted
  - Failure to check for conditionals that may cause the underlying language or hardware system to raise an exception (ex: arithmetic overflow)

# Testing paths

- Examine the method specifications (preconditions) & all paths through method to generate unique test cases for testing.

```
/* REQUIRES: x >= 0 && y >= 10 */
```

```
public static int calc(int x, int y) { ... }
```

Translate paths to test cases:

```
x = 0, y = 10 (x == 0 && y == 10)
```

```
x = 5, y = 10 (x > 0 && y == 10)
```

```
x = 0, y = 15 (x == 0 && y > 10)
```

```
x = 5, y = 15 (x > 0 && y > 10)
```

Add fail test cases:

```
x = -1, y = 10 (x < 0 && y == 10)
```

```
x = -1, y = 15 (x < 0 && y > 10)
```

```
x = -1, y = 9 (x < 0 && y < 10)
```

```
x = 0, y = 9 (x == 0 && y < 10)
```

```
x = 1, y = 9 (x > 0 && y < 10)
```

# Boundary Conditions

- A JUnit test class for the boundary conditions for withdrawals from a BankAccount
  - Standard Withdrawal: Arrange an account with \$100, withdraw \$30. Assert that the method returns true and the new balance is \$70.
  - Boundary Condition (Exact Balance): Arrange an account with \$100, withdraw exactly \$100. Assert that the method returns true and the balance becomes \$0.
  - Boundary Condition (Overdraft): Arrange an account with \$100, attempt to withdraw \$100.01 (one cent over). Assert that the method returns false and the balance remains \$100.

```

import static org.junit.jupiter.api.Assertions.*;
import org.junit.jupiter.api.Test;
import org.junit.jupiter.api.DisplayName;
class BankAccountTest {
    @Test
    @DisplayName("Withdrawing a valid amount within the balance limit")
    void testStandardWithdrawal() {
        // 1. Arrange
        BankAccount account = new BankAccount(100.0);
        // 2. Act
        boolean result = account.withdraw(30.0);
        // 3. Assert
        assertTrue(result, "Withdrawal should return true");
        assertEquals(70.0, account.getBalance(), "Balance should be 70.0");
    }
    @Test
    @DisplayName("Boundary Condition: Withdrawing the exact total balance")
    void testExactBalanceWithdrawal() {
        BankAccount account = new BankAccount(100.0);
        boolean result = account.withdraw(100.0);
        assertTrue(result, "Withdrawal of exact balance should return true");
        assertEquals(0.0, account.getBalance(), "Balance should drop exactly to 0.0");
    }
    @Test
    @DisplayName("Boundary Condition: Requesting an overdraft by just one cent")
    void testOverdraftBoundary() {
        BankAccount account = new BankAccount(100.0);
        boolean result = account.withdraw(100.01);
        assertFalse(result, "Withdrawal exceeding balance should return false");
        assertEquals(100.0, account.getBalance(), "Balance should remain unchanged at 100.0");
    }
}

```

method name / parameters	description
assertTrue( <i>test</i> ) assertTrue("message", <i>test</i> )	Causes this test method to fail if the given boolean test is not true.
assertFalse( <i>test</i> ) assertFalse("message", <i>test</i> )	Causes this test method to fail if the given boolean test is not false.
assertEquals( <i>expectedValue</i> , <i>value</i> ) assertEquals("message", <i>expectedValue</i> , <i>value</i> )	Causes this test method to fail if the given two values are not equal to each other. (For objects, it uses the equals method to compare them.) The first of the two values is considered to be the result that you expect; the second is the actual result produced by the class under test.
assertNotEquals( <i>value1</i> , <i>value2</i> ) assertNotEquals("message", <i>value1</i> , <i>value2</i> )	Causes this test method to fail if the given two values <i>are</i> equal to each other. (For objects, it uses the equals method to compare them.)
assertNull( <i>value</i> ) assertNull("message", <i>value</i> )	Causes this test method to fail if the given value is not null.
assertNotNull( <i>value</i> ) assertNotNull("message", <i>value</i> )	Causes this test method to fail if the given value <i>is</i> null.
assertSame( <i>expectedValue</i> , <i>value</i> ) assertSame("message", <i>expectedValue</i> , <i>value</i> ) assertNotSame( <i>value1</i> , <i>value2</i> ) assertNotSame("message", <i>value1</i> , <i>value2</i> )	Identical to assertEquals and assertNotEquals respectively, except that for objects, it uses the == operator rather than the equals method to compare them. (The difference is that two objects that have the same state might be equals to each other, but not == to each other. An object is only == to itself.)
fail() fail("message")	Causes this test method to fail.

# Glass-box testing

- Black-box testing is generally not enough.
- For Glass-box testing, the code of a program being tested is taken into account
- Path-completeness:
  - Test cases are generated to exercise each path through a program.
  - May be insufficient to catch all errors.
  - Can be used effectively only for a program fragment that contains a reasonable number of paths to test.

# Glass-box testing

- Consider a method that calculates a user's shipping discount based on their loyalty tier and order total:

```
public double calculateShipping(String tier, double totalOrder) {  
    if ("Platinum".equals(tier)) {  
        return 0.00; // Free shipping for Platinum  
    } else if ("Gold".equals(tier)) {  
        if (totalOrder >= 50.00)  
            return 0.00; // Free shipping for Gold if order is $50+  
        else  
            return 5.00; // $5 shipping for Gold under $50  
    } else  
        return 10.00; // Flat $10 shipping for everyone else  
}
```

# Glass-box testing

- Structural Analysis & Path Completeness Table map out every single independent path through a program fragment to achieve path-completeness meaning that test cases are systematically generated to exercise every possible branch route from the method's entry point to its exit point.
  - Path ID: A unique identifier (e.g., Path A, Path 1) for tracking and cross-referencing with automated test cases.
  - Input Variables: Separate columns for every parameter or configuration variable that influences an if, else if, else, or loop condition.
  - Expected Output: The exact return value, object state change, or exception that the code is structured to produce when following that specific path.
  - Core Branch Condition / Internal Logic Path: A brief explanation detailing exactly which internal branch conditions are evaluated as true or false to route execution along that path.

# Glass-box testing

- How to Perform the Structural Analysis:
  - Identify Decision Points: Look for every conditional operator or control block (if, switch, loops).
  - Trace Combinations: Chart every unique outcome of those decisions. For example, if you have a nested if structure, you must account for when the outer condition is true/false, and when the inner conditions are true/false.
  - Find the Input Configurations: Work backward from the path to deduce the exact input values needed to force the execution stream down that specific logical line.

# Glass-box testing

- Why Use a Path Completeness Table?
  - Discovers Hidden Logic Errors: It catches edge cases where a particular path or handling of a special condition was omitted by the programmer.
  - Ensures Code Coverage: It ensures that no dead code blocks exist and that every line of code written is verified at least once.

# Glass-box testing

- Consider the method that calculates a user's shipping discount based on their loyalty tier and order total:

```
public double calculateShipping(String tier, double totalOrder) {  
    if ("Platinum".equals(tier)) {  
        return 0.00; // Free shipping for Platinum  
    } else if ("Gold".equals(tier)) {  
        if (totalOrder >= 50.00)  
            return 0.00; // Free shipping for Gold if order is $50+  
        else  
            return 5.00; // $5 shipping for Gold under $50  
    } else  
        return 10.00; // Flat $10 shipping for everyone else  
}
```

# Glass-box testing

- Structural Analysis & Path Completeness Table

Path ID	tier Input	totalOrder Input	Expected Return Value	Core Branch Condition / Internal Logic Path
Path 1	"Platinum"	30.00 (any value)	0.00	Evaluates the first if statement as true. Returns free shipping immediately.
Path 2	"Gold"	60.00	0.00	First if is false, else if ("Gold") is true. Inner boundary condition <code>totalOrder &gt;= 50.00</code> evaluates to true.
Path 3	"Gold"	20.00	5.00	First if is false, else if ("Gold") is true. Inner boundary condition <code>totalOrder &gt;= 50.00</code> evaluates to false (else branch).
Path 4	"Regular" (or any other)	100.00 (any value)	10.00	All previous if and else if checks evaluate to false. Execution falls entirely through to the final catch-all else block.

```

import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.assertEquals;
public class ShippingCalculatorTest {
    private ShippingCalculator calculator = new ShippingCalculator();
    @Test
    public void testPlatinumTier_GetsFreeShipping() {
        // Arrange
        String tier = "Platinum";
        double totalOrder = 30.00;
        // Act
        double actualShipping = calculator.calculateShipping(tier, totalOrder);
        // Assert
        assertEquals(0.00, actualShipping, 0.001);
    }
    @Test
    public void testGoldTier_WithOrderOverFifty_GetsFreeShipping() {
        String tier = "Gold";
        double totalOrder = 60.00;
        double actualShipping = calculator.calculateShipping(tier, totalOrder);
        assertEquals(0.00, actualShipping, 0.001);
    }
    @Test
    public void testGoldTier_WithOrderUnderFifty_PaysFiveDollars() {
        String tier = "Gold";
        double totalOrder = 20.00;
        double actualShipping = calculator.calculateShipping(tier, totalOrder);
        assertEquals(5.00, actualShipping, 0.001);
    }
    @Test
    public void testSilverTier_PaysFlatTenDollars() {
        String tier = "Silver";
        double totalOrder = 100.00;
        double actualShipping = calculator.calculateShipping(tier, totalOrder);
        assertEquals(10.00, actualShipping, 0.001);
    }
}

```

# Glass-box testing

- Why 0.001 is inside the assertEquals?
  - When testing double or float types in Java, you should always pass a third argument called a delta (tolerance). Because computers handle floating-point math with minor precision quirks, checking if a double exactly equals another double can cause flaky tests. 0.001 means "as long as the numbers are within \$0.001 of each other, pass the test."

# Notes on Static import

- Static import is a feature introduced in the Java programming language that allows members (fields and methods) defined in a class as public static to be used in Java code without specifying the class in which the field is defined.

- The mechanism can be used to reference individual members of a class:

```
import static java.lang.Math.PI;  
import static java.lang.Math.pow;
```

- or all the static members of a class:

```
import static java.lang.Math.*;
```

# Static import example

```
import static java.lang.Math.*;
```

```
// OR
```

```
// import static java.lang.Math.PI;
```

```
// import static java.lang.Math.pow;
```

```
import static java.lang.System.out;
```

```
public class HelloWorld {  
    public static void main(String[] args) {  
        out.println("Hello World!");  
        out.println("A circle with a diameter of 5 cm has:");  
        out.println("A circumference of " + (PI * 5) + " cm");  
        out.println("And an area of " + (PI * pow(2.5, 2))  
            + " sq. cm");  
    }  
}
```

# Notes on Assertions

- An assertion is a Java statement that enables you to assert an assumption about your program.
- An assertion contains a Boolean expression that should be true during program execution.
- Assertions can be used to assure program correctness and avoid logic errors.

# Declaring Assertions

- An assertion is declared using the Java keyword **assert** in JDK 1.5 as follows:

```
assert assertion; //OR
```

```
assert assertion : detailMessage;
```

where `assertion` is a Boolean expression and `detailMessage` is a primitive-type or an Object value.

# Executing Assertions Example

```
public class AssertionDemo {  
    public static void main(String[] args) {  
        int i; int sum = 0;  
        for (i = 0; i < 10; i++) {  
            sum += i;  
        }  
        assert i==10;  
        assert sum>10 && sum<5*10 : "sum is " + sum;  
    }  
}
```

# Executing Assertions

- When an assertion statement is executed, Java evaluates the assertion.
  - If it is false, an `AssertionError` will be thrown.
  - The `AssertionError` class has a no-arg constructor and seven overloaded single-argument constructors of type `int`, `long`, `float`, `double`, `boolean`, `char`, and `Object`.
  - For the first `assert` statement with no detail message, the no-arg constructor of `AssertionError` is used.
  - For the second `assert` statement with a detail message, an appropriate `AssertionError` constructor is used to match the data type of the message.
  - Since `AssertionError` is a subclass of `Error`, when an assertion becomes false, the program displays a message on the console and exits.

# Running Programs with Assertions

- By default, the assertions are disabled at runtime. To enable it, use the switch `-enableassertions`, or `-ea` for short, as follows:

```
java -ea AssertionDemo
```

```
public class AssertionDemo {  
    public static void main(String[] args) {  
        int i; int sum = 0;  
        for (i = 0; i < 10; i++) {  
            sum += i;  
        }  
        assert i!=10;  
    }  
}
```

```
Exception in thread "main" java.lang.AssertionError  
at AssertionDemo.main(AssertionDemo.java:7)
```

# Running Programs with Assertions

- In Java, assertions are disabled by default, so you need to enable them:
- Enable assertions in Eclipse
  - Right-click your Java file → Select Run As → Run Configurations...
  - Go to the Arguments tab
  - In the VM arguments box, add:
    - -ea
  - Click Run

# Using Exception Handling or Assertions?

- Assertion should not be used to replace exception handling.
  - Exception handling deals with unusual circumstances during program execution.
  - Assertions are to assure the correctness of the program.
  - Exception handling addresses robustness and assertion addresses correctness.
  - Assertions are used for internal consistency and validity checks.
  - Assertions are checked at runtime and can be turned on or off at startup time.

# Using Exception Handling or Assertions?

- Do not use assertions for argument checking in public methods:
  - Valid arguments that may be passed to a public method are considered to be part of the method's contract.
  - The contract must always be obeyed whether assertions are enabled or disabled.
  - For example, the following code in the Circle class should be rewritten using exception handling:

```
public void setRadius(double newRadius) {  
    assert newRadius >= 0;  
    radius = newRadius;  
}
```

# Using Exception Handling or Assertions?

- Use assertions to reaffirm assumptions.
  - This gives you more confidence to assure correctness of the program.
  - A common use of assertions is to replace assumptions with assertions in the code.
  - A good use of assertions is place assertions in a switch statement without a default case. For example:

```
switch (month) {  
    case 1: ... ; break;  
    case 2: ... ; break;  
    ...  
    case 12: ... ; break;  
    default: assert false : "Invalid month: " + month;  
}
```
