Hashing

CSE260, Computer Science B: Honors
Stony Brook University

http://www.cs.stonybrook.edu/~cse260
Objectives

- To understand what *hashing* is and what hashing is used for
- To obtain the hash code for an object and design the hash function to map a key to an index
- To handle collisions using open addressing
- To know the differences among *linear probing*, *quadratic probing*, and *double hashing*
- To handle collisions using separate chaining
- To understand the *load factor* and the need for *rehashing*
- To implement *MyHashMap* using hashing
- To implement *MyHashSet* using hashing
Hashing and Maps

- Why hashing?
  - O(1) time to search, insert, and delete an element in a map or a set vs. O(logn) time in a well-balanced search tree

- A map (aka. dictionary, a hash table, or an associative array) is a data structure that stores entries, where each entry contains two parts: key (also called a search key) and value
  - The key is used to search for the corresponding value
  - For example, a dictionary can be stored in a map, where the words are the keys and the definitions of the words are the values
Hashing

• If you know the index of an element in the array, you can retrieve the element using the index in $O(1)$ time
  • So, can we store the values in an array and use the key as the index to find the value?
  • The answer is yes if you can map a key to an index

• The array that stores the values is called a hash table

• The function that maps a key to an index in the hash table is called a hash function

• Hashing is a technique that retrieves the value using the index obtained from key without performing a search
Hash Functions and Hash Codes

- A typical **hash function** first converts a search key to an **integer** value called a **hash code**, then compresses the hash code into an index to the hash table.
- Java’s root class **Object** has the **hashCode** method, which returns an integer hash code -- by default, the method returns the **memory address** for the object.
- You should override the **hashCode** method whenever the **equals** method is overridden to **ensure that two equal objects return the same hash code**.
- During the execution of a program, invoking the **hashCode** method multiple times on the same object returns the same integer, provided that the object’s data are not changed.
- Two unequal objects may have the same hash code, but you should implement the **hashCode** method to avoid too many such cases.
Hash Codes for Primitive Types

- The types `byte`, `short`, `int`, and `char` are simply casted into `int`
  - two different search keys of any one of these types will have different hash codes
- For a search key of the type `float`, return an `int` value whose bit
  representation is the same as the bit representation for the floating number
  - use `Float.floatToIntBits(key)` to get the the hash code
- For a search key of the type `long`, simply casting it to `int` would not be a
  good choice, because all keys that differ in only the first 32 bits will have the
  same hash code

```
System.out.println((int)(4294967296L)); // 0
System.out.println((int)(4294967297L)); // 1
System.out.println((int)(4294967298L)); // 2
System.out.println((int)(4294967299L)); // 3
```

- Divide the 64 bits into two halves and perform the exclusive or operation to
  combine the two halves (this process is called `folding`)

```
hashCode = (int)(key ^ (key >> 32));
```

```
1010110 ^ 0110111 yields 1100001
```
Hash Codes for Primitive Types

- For a search key of the type `double`, first convert it to a `long` value using the `Double.doubleToLongBits` method, and then perform a folding as follows:

```java
long bits = Double.doubleToLongBits(key);
int hashCode = (int)(bits ^ (bits >>> 32));
```
Hash Codes for Strings

- An intuitive approach is to sum the Unicode of all characters as the hash code for the string
  - This approach may work if two search keys in an application don’t contain the same letters, but it fails otherwise, e.g., *tod* and *dot*
- A better approach is to generate a hash code that takes the position of characters into consideration:
  \[ s_0 \times b^{(n-1)} + s_1 \times b^{(n-2)} + \ldots + s_{n-1} \]

where \( s_i \) is \( s \text{.charAt}(i) \)

- Using Horner’s rule for polynomial evaluation, the hash code can be calculated efficiently as follows:
  \[
  (\ldots ((s_0 \times b + s_1)b + s_2)b + \ldots + s_{n-2})b + s_{n-1}
  \]
- This expression is a polynomial for some positive \( b \), so this is called a *polynomial hash code*
Hash Codes for Strings

- The hash computation can cause an overflow for long strings, but arithmetic overflow is ignored in Java.
- You should choose an appropriate value \( b \) to minimize collisions.
- Experiments show that good choices for \( b \) are 31, 33, 37, 39, and 41.
- In the String class, the `hashCode` is overridden using the polynomial hash code with \( b \) being 31.
Compressing Hash Codes

• The hash code for a key can be a large integer that is out of the range for the hash-table index
  • you need to scale it down to fit in the index’s range
• Assume the index for a hash table is between 0 and $N-1$ -- the most common way to scale an integer is $h(\text{hashCode}) = \text{hashCode} \mod N$
• To ensure that the indices are spread evenly, choose $N$ to be a prime number greater than 2
  • However, it is time consuming to find a large prime number
Compressing Hash Codes

- In the Java API implementation for `java.util.HashMap`, \( N \) is set to a value of the power of 2 because then
  \[
  h(\text{hashCode}) = \text{hashCode} \mod N
  \]
  is the same as
  \[
  h(\text{hashCode}) = \text{hashCode} \& (N - 1)
  \]
  Bitwise conjunction
  \( \& \) can be performed much faster than the \( \mod \) operator
- The bitwise operations are much faster than the multiplication, division, and remainder operations -- you should replace these operations with the bitwise operations whenever possible
- For example, assume \( N = 4 \) and \( \text{hashCode} = 11 \)
  \[
  11 \mod 4 = 3
  \]
  \[
  (01011) \& (00011) = (11)\]

(c) Paul Fodor & Pearson Education
Compressing Hash Codes

• To ensure that the hashing is evenly distributed, a supplemental hash function is also used along with the primary hash function in the implementation of `java.util.HashMap`

```java
private static int supplementalHash(int h) {
    h ^= (h >>> 20) ^ (h >>> 12);
    return h ^ (h >>> 7) ^ (h >>> 4);
}
```

• The complete hash function is defined as:

\[
h(\text{hashCode}) = \text{supplementalHash}(\text{hashCode}) \mod N
\]

is the same as

\[
h(\text{hashCode}) = \text{supplementalHash}(\text{hashCode}) \& (N - 1)
\]

since \( N \) is a power of \( 2 \)
Hash Function and Hash Codes

- A typical hash function first converts a search key to an integer value called a **hash code**, and then compresses the hash code into an index to the hash table.

```
i = hash(key)
```

![Hash Function Diagram]

An entry
Linear Probing

- If an index position is already occupied, **linear probing** algorithm looks at the consecutive cells beginning at index $k$. 

<table>
<thead>
<tr>
<th>Index</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>44</td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>16</td>
</tr>
<tr>
<td>6</td>
<td>28</td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>21</td>
</tr>
</tbody>
</table>

For simplicity, only the keys are shown and the values are not shown. Here $N$ is 11 and index $=\text{key} \mod N$. 

New element with key 26 to be inserted 

Probe 3 times before finding an empty cell
Quadratic Probing

- **Quadratic probing** can avoid the clustering problem in linear probing:

  New element with key 26 to be inserted

  Quadratic probe 2 times before finding an empty cell

  For simplicity, only the keys are shown and not the values. Here $N$ is 11 and index = $\text{key} \mod N$. 

  - 0: key: 44
  - 1:
  - 2:
  - 3:
  - 4: key: 4
  - 5: key: 16
  - 6: key: 28
  - 7:
  - 8:
  - 9:
  - 10: key: 21
Handling Collisions Using Separate Chaining

- The *separate chaining scheme* places all entries with the same hash index into the same location, rather than finding new locations.
- Each location in the separate chaining scheme is called a *bucket*.
- A bucket is a container that holds multiple entries:

```
key: 44
key: 4
key: 16
key: 26
key: 28
key: 21
```

For simplicity, only the keys are shown, and not the values. Here $N$ is 11 and index = key % N.
Double Hashing

- **Double hashing** uses a secondary hash function on the keys to determine the increments to avoid the clustering problem.

\[ h'(k) = 7 - k \mod 7; \]
import java.util.HashMap;

public class HashMapDemo {
    public static void main(String[] args) {
        HashMap<String, Integer> map;
        map = new HashMap<>();
        map.put("Smith", 30);
        map.put("Anderson", 31);
        map.put("Lewis", 29);
        map.put("Cook", 29);
        map.put("Smith", 65);

        System.out.println("Entries in map: ") + map);
        System.out.println("The age for " + "Lewis is " + map.get("Lewis");
        System.out.println("Is Smith in the map? " + map.containsKey("Smith");
        System.out.println("Is age 33 in the map? " + map.containsValue(33));

        map.remove("Smith");
        System.out.println("Entries in map: ") + map);
        map.clear();
        System.out.println("Entries in map: ") + map);
    }
}

«interface»
MyMap<K, V>
+clear(): void
+containsKey(key: K): boolean
+containsValue(value: V): boolean
+entrySet(): Set<Entry<K, V>>
+get(key: K): V
+isEmpty(): boolean
+keySet(): Set<K>
+put(key: K, value: V): V
+remove(key: K): void
+size(): int
+values(): Set<V>

Removes all entries from this map.
Returns true if this map contains an entry for the specified key.
Returns true if this map maps one or more keys to the specified value.
Returns a set consisting of the entries in this map.
Returns a value for the specified key in this map.
Returns true if this map contains no mappings.
Returns a set consisting of the keys in this map.
Puts a mapping in this map.
Removes the entries for the specified key.
Returns the number of mappings in this map.
Returns a set consisting of the values in this map.

MyHashMap<K, V>
+MyHashMap()
+MyHashMap(capacity: int)
+MyHashMap(capacity: int, loadFactorThreshold: float)

Creates an empty map with default capacity 4 and default load factor threshold 0.75f.
Creates a map with a specified capacity and default load factor threshold 0.75f.
Creates a map with a specified capacity and load factor threshold.

MyMap.Entry<K, V>
-key: K
-value: V
+Entry(key: K, value: V)
+getKey(): K
+getValue(): V

Constructs an entry with the specified key and value.
Returns the key in the entry.
Returns the value in the entry.
```
public interface MyMap<K, V> {
    /** Remove all of the entries from this map */
    public void clear();

    Entries in map: []
Implementing Set Using Hashing

```java
interface MySet<E>

+ clear(): void
+ contains(e: E): boolean
+ add(e: E): boolean
+ remove(e: E): boolean
+ isEmpty(): boolean
+ size(): int

MyHashSet<E>

+ MyHashSet()
+ MyHashSet(capacity: int)
+ MyHashSet(capacity: int, loadFactorThreshold: float)
```

- Removes all elements from this set.
- Returns true if the element is in the set.
- Adds the element to the set and returns true if the element is added successfully.
- Removes the element from the set and returns true if the set contained the element.
- Returns true if this set does not contain any elements.
- Returns the number of elements in this set.

- Creates an empty set with default capacity 4 and default load factor threshold 0.75f.
- Creates a set with a specified capacity and default load factor threshold 0.75f.
- Creates a set with a specified capacity and load factor threshold.
public interface MySet\<E\> extends java.lang.Iterable\<E\> {
    /** Remove all elements from this set */
