From Processes to Threads

Don Porter

Processes, Threads and Processors

- Hardware can execute $N$ instruction streams at once
  - Uniprocessor, $N==1$
  - Dual-core, $N==2$
  - Sun’s Niagara T2 (2007) $N == 64$, but 8 groups of 8

- An OS can run 1 process on each processor at the same time
  - Concurrent execution increases performance

- An OS can run 1 thread on each processor at the same time
Processes and Threads

- Process abstraction combines two concepts
  - Concurrency
    - Each process is a sequential execution stream of instructions
  - Protection
    - Each process defines an address space
    - Address space identifies all addresses that can be touched by the program

- Threads
  - Key idea: separate the concepts of concurrency from protection
  - A thread is a sequential execution stream of instructions
  - A process defines the address space that may be shared by multiple threads
  - Threads can execute on different cores on a multicore CPU (parallelism for performance) and can communicate with other threads by updating memory
Example Redux

Virtual Address Space

- 2 threads requires 2 stacks in the process
- No problem!
- Kernel can schedule each thread separately
  - Possibly on 2 CPUs
  - Requires some extra bookkeeping
Consider the following code fragment

\[
\text{for}(k = 0; k < n; k++)
\]
\[
\quad a[k] = b[k] \times c[k] + d[k] \times e[k];
\]

Is there a missed opportunity here? On a Uni-processor? On a Multi-processor?
The Case for Threads

Consider a Web server
  get network message (URL) from client
  get URL data from disk
  compose response
  send response

How well does this web server perform?
void fn1(int arg0, int arg1, ...) {...}

main() {
  ...
  tid = CreateThread(fn1, arg0, arg1, ...);
  ...
}

At the point CreateThread is called, execution continues in parent thread in main function, and execution starts at fn1 in the child thread, both in parallel (concurrently)
Introducing Threads

- A thread represents an abstract entity that executes a sequence of instructions
  - It has its own set of CPU registers
  - It has its own stack
  - There is no thread-specific heap or data segment (unlike process)

- Threads are lightweight
  - Creating a thread more efficient than creating a process.
  - Communication between threads easier than btw. processes.
  - Context switching between threads requires fewer CPU cycles and memory references than switching processes.
  - Threads only track a subset of process state (share list of open files, pid, …)

- Examples:
  - OS-supported: Windows’ threads, Sun’s LWP, POSIX threads
  - Language-supported: Modula-3, Java
    - These are possibly going the way of the Dodo
Context switch time for which entity is greater?

1. Process
2. Thread
How Can it Help?

- How can this code take advantage of 2 threads?
  
  ```c
  for(k = 0; k < n; k++)
      a[k] = b[k] * c[k] + d[k] * e[k];
  ```

- Rewrite this code fragment as:
  
  ```c
  do_mult(l, m) {
      for(k = l; k < m; k++)
          a[k] = b[k] * c[k] + d[k] * e[k];
  }

  main() {
      CreateThread(do_mult, 0, n/2);
      CreateThread(do_mult, n/2, n);
  }
  ```

- What did we gain?
How Can it Help?

- Consider a Web server
  
  Create a number of threads, and for each thread do
  
  - get network message from client
  
  - get URL data from disk
  
  - send data over network

- What did we gain?
Overlapping Requests (Concurrency)

- **Request 1**
  - Thread 1
  - get network message (URL) from client
  - get URL data from disk
  - send data over network
  - (disk access latency)

- **Request 2**
  - Thread 2
  - get network message (URL) from client
  - get URL data from disk
  - send data over network
  - (disk access latency)

- **Total time is less than request 1 + request 2**
Why threads? (summary)

- Computation that can be divided into concurrent chunks
  - Same Instruction (or operation), Multiple Data (SIMD – easy)
  - Harder to identify parallelism in more complex cases
- Overlapping blocking I/O with computation
  - If my web server blocks on I/O for one client, why not work on another client’s request in a separate thread?
  - Other abstractions we won’t cover (e.g., events)
Threads have their own...?

1. CPU
2. Address space
3. PCB
4. Stack 😊
5. Registers 😊
<table>
<thead>
<tr>
<th>Threads</th>
<th>Processes</th>
</tr>
</thead>
<tbody>

</table>
Implementing Threads

- Processes define an address space; threads share the address space

- Process Control Block (PCB) contains process-specific information
  - Owner, PID, heap pointer, priority, active thread, and pointers to thread information

- Thread Control Block (TCB) contains thread-specific information
  - Stack pointer, PC, thread state (running, ...), register values, a pointer to PCB, ...
Threads’ Life Cycle

- Threads (just like processes) go through a sequence of start, ready, running, waiting, and done states.
Threads have the same scheduling states as processes

1. True
2. False

- In fact, OSes generally schedule *threads* to CPUs, not processes
User-level vs. Kernel-level threads

- **User-level threads (M to 1 model)**
  - + Fast to create and switch
  - + Natural fit for language-level threads
  - - Duplicate effort (2 thread schedulers)
    - The schedulers can fight with each other
  - - All user-level threads in process block on OS calls
    - E.g., read from file can block all threads

- **Kernel-level threads (1 to 1 model)**
  - + Kernel-level threads do not block process for syscall
  - + Only one scheduler (and kernel has global view)
  - - Can be difficult to make efficient (create & switch)
Kernel-level threads have won for systems
- Linux, Solaris 10, Windows
- pthreads tend to be kernel-level threads

User-level threads still used in some Java runtimes
- User tells JVM how many underlying system threads
  - Default: 1 system thread
  - Java runtime intercepts blocking calls, makes them non-blocking
  - JNI code that makes blocking syscalls can block JVM
  - JVMs are phasing this out because kernel threads are efficient enough and intercepting system calls is complicated

Kernel-level thread vs. process
- Each process requires its own page table & hardware state (significant on the x86)
There is a 25+ year history of debating user vs. kernel threads

- These discussions are couched in grand principles

The real issue is simple: Performance!!

- If the kernel implementation of thread context switching is slow, everyone starts writing user-level thread packages
  - Java did this for a while
- If the kernel implementation gets faster, everyone just uses kernel threads, since they are easier
  - Java does this now, Linux 2.6 overhauled its thread implementation
Latency and Throughput

- Latency: time to complete an operation
- Throughput: work completed per unit time
- Multiplying vector example: reduced latency
- Web server example: increased throughput
- Consider plumbing
  - Low latency: turn on faucet and water comes out
  - High bandwidth: lots of water (e.g., to fill a pool)
- What is “High speed Internet?”
  - Low latency: needed to interactive gaming
  - High bandwidth: needed for downloading large files
  - Marketing departments like to conflate latency and bandwidth…
Relationship between Latency and Throughput

- Latency and bandwidth only loosely coupled
  - Henry Ford: assembly lines increase bandwidth without reducing latency

- My factory takes 1 day to make a Model-T ford.
  - But I can start building a new car every 10 minutes
  - At 24 hrs/day, I can make 24 * 6 = 144 cars per day
  - A special order for 1 green car, still takes 1 day
  - Throughput is increased, but latency is not.

- Latency reduction is difficult

- Often, one can buy bandwidth
  - E.g., more memory chips, more disks, more computers
  - Big server farms (e.g., google) are high bandwidth
Can threads improve throughput?
- Yes, as long as there are parallel tasks and CPUs available.

Can threads improve latency?
- Yes, especially when one task might block on another task’s IO.

Can threads harm throughput?
- Yes, each thread gets a time slice.
- If # threads >> # CPUs, the % of CPU time each thread gets approaches 0.

Can threads harm latency?
- Yes, especially when requests are short and there is little I/O.
For CPU-intensive work, applications generally create one thread per CPU.

For work with I/O, the number of threads is tuned to keep the CPU busy but not overloaded:
- E.g., 3 * # CPUs
- Tuning effort often application-specific

Applications like web servers often keep thread pools, or a set of n ready threads:
- New requests are assigned to an existing thread to avoid overloading the system
- Plus, reduce setup/tear down costs!
Thread or Process Pool

- Creating a thread or process for each unit of work (e.g., user request) is dangerous
  - High overhead to create & delete thread/process
  - Can exhaust CPU & memory resource
- Thread/process pool controls resource use
  - Allows service to be well conditioned.
When a user level thread does I/O it blocks the entire process.

1. True 😊
2. False
Lecture Summary

- Understand the distinction between a process and thread
- Understand the motivation for threads
- Kernel vs. User threads
- Concepts of Throughput vs. Latency
- Thread pools
