

A Modular Visual Model for Hybrid Systems

R. Grosu, Th. Stauner, M. Broy
TU München, Germany

Motivation

- The design of **hybrid systems** is a **difficult task**. One has to consider many **different aspects** like **data, behavior, architecture** and **distribution**.
- Moreover it usually **involves people** from **different engineering disciplines**.
- Many modern **SE methods** like **UML, ROOM** and **SDL** recommend the use of **visual specifications**.
- A **formal foundation** is needed however, to **prohibit ambiguities** which may be **fatal** in this context.

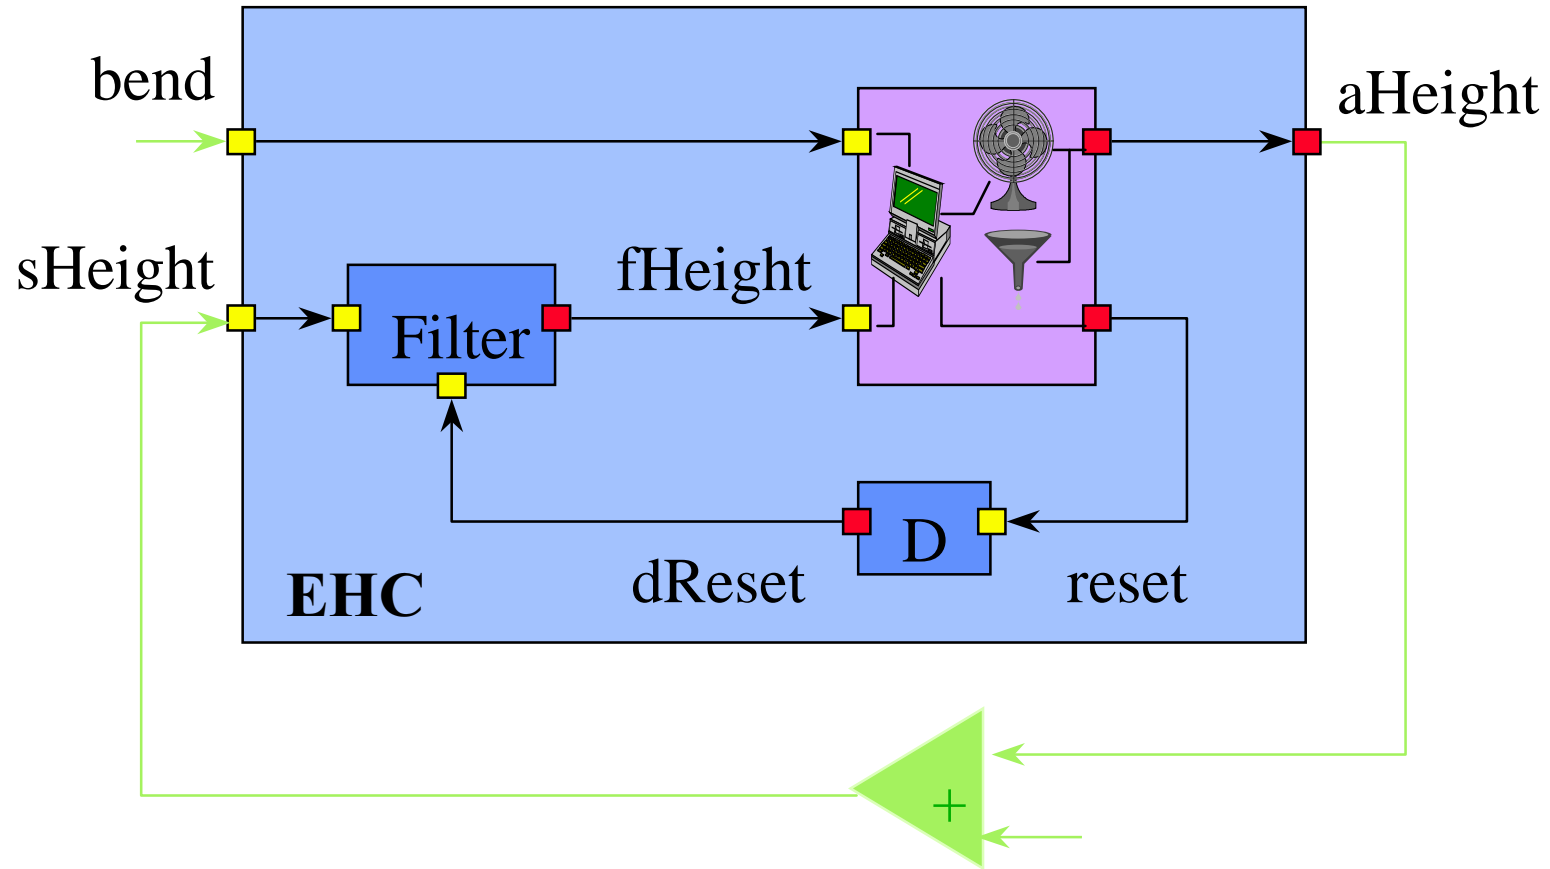

Overview

- **An electronic height control system (BMW).**
- **The computation model.**
- **Hierarchic graphs and their associated models.**
- **Conclusions.**

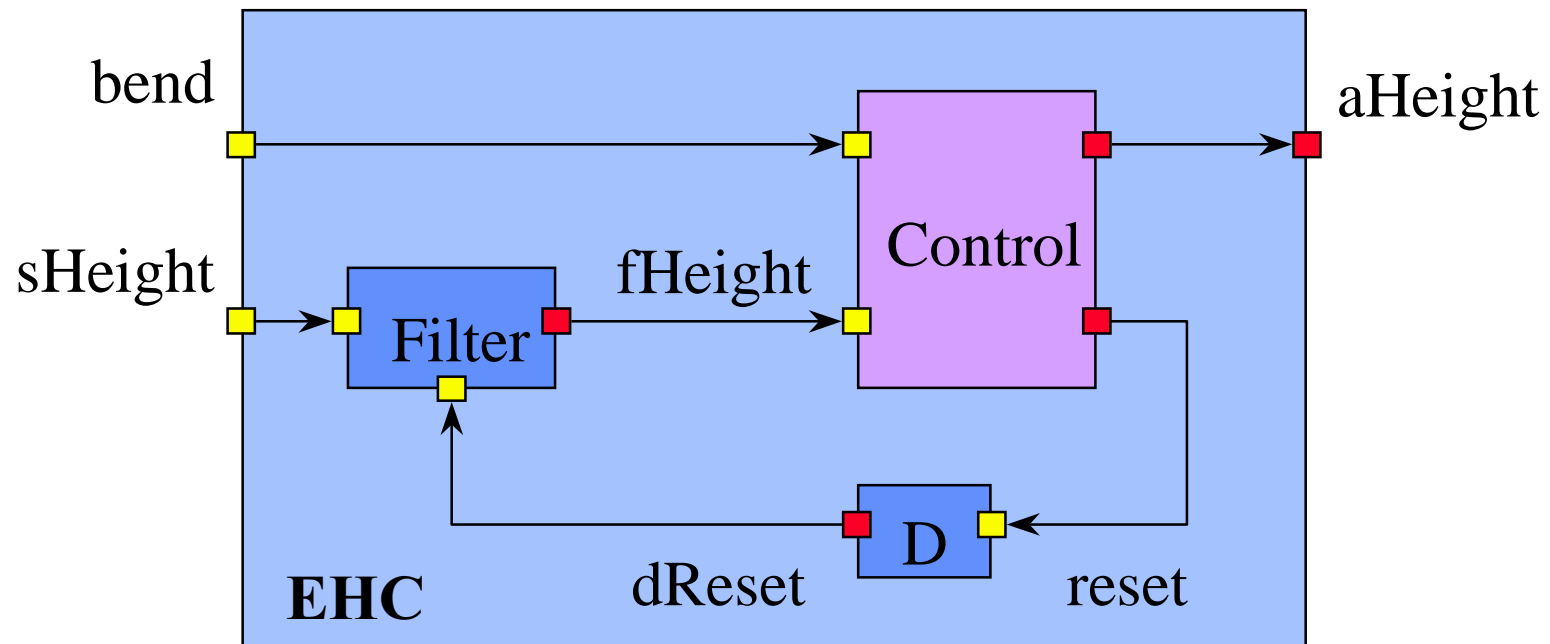

Electronic Height Control System

- Whenever the **chassis level** is **outside of a tolerance interval** it has to be **increased** or **decreased** to get close to the **center** of the interval.
- Very **short deviations** from the tolerance interval should not be **compensated**.
- After a compensation, some **time should pass** before the **actuator** is **switched on again**.
- The chassis level **may not be modified** whenever **the car** is **going through a curve**.

Conclusions

- **HyACharts** allow the **hierarchical specification** of the **structure of a hybrid system**.
 - **Subsystems** may be described with **other formalisms**.
- **HySCharts** allow the **hierarchical specification** of the **behavior of a hybrid system**.
 - Both **discrete** and **continuous** aspects are **integrated** in a uniform way (**activities, preemption, entry/exit actions**).
- **HyACharts** and **HySCharts** are **dual models** of **hierarchic graphs**. Their **formal theory** allows their **verification** and **optimization**.
