Quadrilateral Mesh Generation Theory

∃⊳

Colorable Quad-Mesh

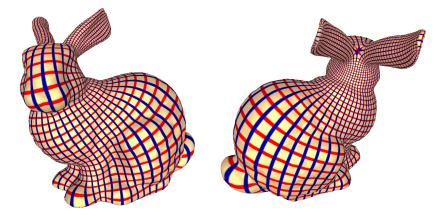

Figure: A red-blue (colorable) Quad-Mesh.

August 17, 2022

Colorable Quad-Mesh

Figure: A quad-mesh induced by a holomorphic 1-form.

Topological Torus

$$\chi = 2 - 2g = 0,$$

$$\sum K = 2\pi\chi = 0.$$

It is impossible to construct a quad mesh on a topological torus with one valence 3 singular point and one valence 5 singular point.

Otherwise, the valence 3 vertex p and the valence 5 vertex q become to the pole and the zero of a meromorphic function. By Abel condition, $\mu(p) = \mu(q)$, the pole and the zero coincide, contradiction.

The number of singularities, and the layouts of separatrices are different.

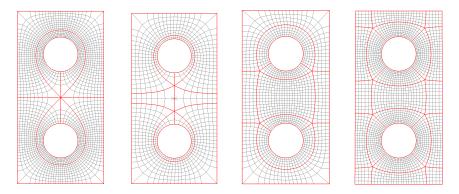

Figure: Quad-meshes with different number of singularities.

David Gu (Stony Brook University)

Computational Conformal Geometry

August 17, 2022

Aim

Establish complete mathematical theory for structural mesh.

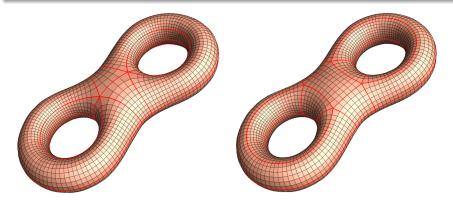

Figure: A quad-mesh of a genus two surface with different number of singularities.

Given a Riemannian surface (S, \mathbf{g}) two quad-meshes are equivalent if they differ by a finite step of subdivisions,

- How many quad-mesh equivalent classes are there on S ? infinite
- What is the dimension of the space of all the quad-mesh equivalent classes on S? Riemann-Roch theorem
- What is the governing equation for the singularities ? Abel-Jacobi theorem

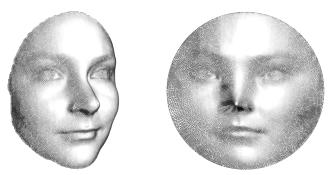

Mathematical View of Structural Quad Mesh

Discrete Metrics

Definition (Discrete Metric)

A Discrete Metric on a triangular mesh is a function defined on the vertices, $I : E = \{all edges\} \rightarrow \mathbb{R}^+$, satisfies triangular inequality.

A mesh has infinite metrics.

Discrete Curvature

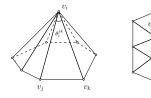

Definition (Discrete Curvature)

Discrete curvature: $K : V = \{vertices\} \rightarrow \mathbb{R}^1$.

$$\mathcal{K}(\mathbf{v}_i) = 2\pi - \sum_{jk} \theta_i^{jk}, \mathbf{v}_i \notin \partial M; \mathcal{K}(\mathbf{v}_i) = \pi - \sum_{jk} \theta_{jk}, \mathbf{v}_i \in \partial M$$

Theorem (Discrete Gauss-Bonnet theorem)

$$\sum_{\nu\notin\partial M} K(\nu) + \sum_{\nu\in\partial M} K(\nu) = 2\pi\chi(M).$$

David Gu (Stony Brook University)

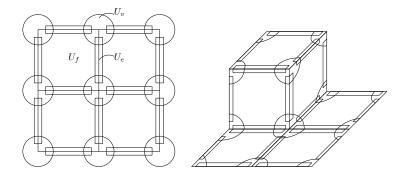

Computational Conformal Geometry

э

Definition (Quad-Mesh Metric)

Given a quad-mesh Q, each face is treated as the unit planar square, this will define a Riemannian metric, the so-called quad-mesh metric \mathbf{g}_{Q} , which is a flat metric with cone singularities.

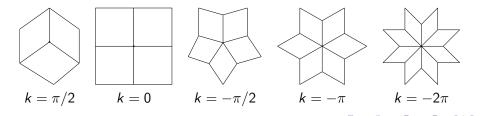

Definition (Curvature)

Given a quad-mesh Q, for each vertex v_i , the curvature is defined as

$$\mathcal{K}(v) = \left\{ egin{array}{cc} rac{\pi}{2}(4-k(v)) & v
otin \partial \mathcal{Q} \ rac{\pi}{2}(2-k(v)) & v \in \partial \mathcal{Q} \end{array}
ight.$$

where k(v) is the topological valence of v, i.e. the number of faces adjacent to v.

Quad-Mesh Metric Conditioins

3 N 3

Theorem (Quad-Mesh Metric Conditions)

Given a quad-mesh Q, the induced quad-mesh metric is \mathbf{g}_{O} , which satisfies the following four conditions:

- Gauss-Bonnet condition:
- Holonomy condition;
- Boundary Alignment condition;
- Finite geodesic lamination condition.

Theorem (Gauss-Bonnet)

Given a quad-mesh Q, the induced metric is g_Q , the total curvature satisfies

$$\sum_{\mathbf{v}_i \in \partial \mathcal{Q}} \mathcal{K}(\mathbf{v}_i) + \sum_{\mathbf{v}_i \notin \partial \mathcal{Q}} \mathcal{K}(\mathbf{v}_i) = 2\pi \chi(\mathcal{Q}).$$

Namely

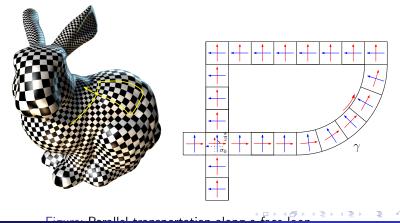

$$\sum_{v_i \in \partial \mathcal{Q}} (2 - k(v_i)) + \sum_{v_i
ot \in \partial \mathcal{Q}} (4 - k(v_i)) = 4\chi(\mathcal{Q}).$$

э

2. Holonomy Condition

Theorem (Holonomy Condition)

Suppose Q is a closed quad-mesh, then the holonomy group induced by \mathbf{g}_Q is a subgroup of the rotation group $\{e^{i\frac{k}{2}\pi}, k \in \mathbb{Z}\}.$

Computational Conformal Geometry

3. Boundary Alignment Condition

Definition (Boundary Alignment Condition)

Given a quad-mesh Q, with induced metric \mathbf{g}_{Q} , one can define a global cross field by parallel transportation, which is aligned with the boundaries.

 Figure: Aligned and mis-aligned with the inner boundaries
 E
 Inner boundaries

3. Boundary Alignment Condition

Definition (Boundary Alignment Condition)

Given a quad-mesh Q, with induced metric \mathbf{g}_{Q} , one can define a global cross field by parallel transportation, which is aligned with the boundaries.

 Figure: Aligned and mis-aligned with the inner boundaries

4. Finite Geodesic Lamination Condition

Definition (Finite Geodesic Lamination Condition)

The stream lines parallel to the cross field are finite geodesic loops. This is the finite geodesic lamination condition.

A genus one closed surface S, which is a polycube surface (union of canonical unit cubes). The holomorphic one form $\omega \in \Omega^1(S)$.

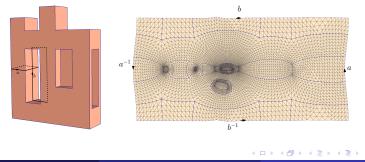

Genus One Polycube Surface Example

The homology basis is $\{a, b\}$, the surface is sliced along $\{a, b\}$ to get a fundamental domain D, $\partial D = abab^{-1}b^{-1}$. The conformal mapping $\mu : D \to \mathbb{C}$ is given by

$$\mu(q) = \int_{p}^{q} \omega,$$

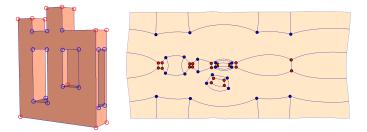

where p is a base point and the integration path is arbitrarily chosen.

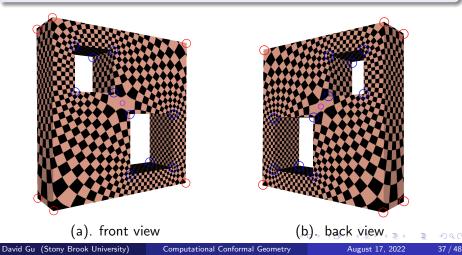

35 / 48

Suppose q_i 's are poles (degree 3), p_j 's are zeros (degree 5), then we have found that the number of poles equals to that of the zeros, furthermore,

$$\sum_{j=1}^{22} \mu(p_j) - \sum_{i=1}^{22} \mu(q_i) = 0.$$

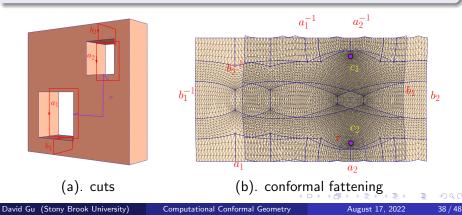

la Suppose S is a genus two polycube surface, ω is a holomorphic one-form. The red circles show the poles (degree 3), the blue circles show the zeros (degree 5), the purple circles the zeros of ω .

The surface is sliced along a_1, b_1, a_2, b_2, τ , and integrate ω to obtain $\mu: S \to \mathbb{C}$

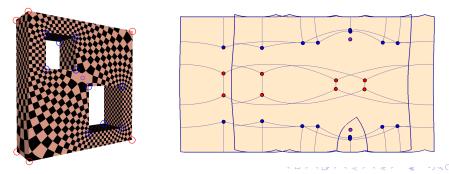

$$\mu(q) = \int_{p}^{q} \omega,$$

it branch covers the plane, the branching points are zeros of ω , c_1, c_2 .

Suppose p_i 's are zeros (degree 5), q_j 's are poles (degree 3), c_k 's are branch points, then we have

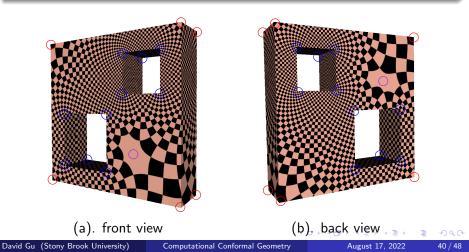

$$\sum_{i=1}^{16} \mu(\mathbf{p}_i) - \sum_{j=1}^{8} \mu(\mathbf{q}_j) = 4 \sum_{k=1}^{2} \mu(\mathbf{c}_k).$$
