

CSE508 Network Security

3/7/2016 **SSL/TLS**

Michalis Polychronakis
Stony Brook University

SSL (Secure Socket Layer)

TLS (Transport Layer Security)

Most widely used protocol(s) for encrypted data transmission

Same basic design, different crypto algorithms

Designed to provide secure communication over the insecure internet

Authentication, confidentiality, and integrity

Used in many services and secure versions of protocols

HTTP, POP, IMAP, SMTP, OpenVPN, CalDAV, CardDAV, LDAP, NNTP, FTP, IRC, SIP, ...

Separate port number HTTPS: 443, FTPS: 990, IMAPS: 993, ...

History

NETSCAPE®

SSL developed at Netscape

- v1: never released
- v2 (1994): serious weaknesses
- v3 (1995): re-design, basis of what we use today

TLS working group was formed to migrate SSL to IETF

- TLS 1.0 (1999): minor differences but incompatible with SSL 3 (different crypto algorithms)
- TLS 1.1 (2006): mostly security fixes, TLS extensions
- TLS 1.2 (2008): authenticated encryption, more flexible

Endless cycle of vulnerabilities and improvements

Insecure renegotiation, RC4 weaknesses, compression side channels, padding oracle attacks, buggy implementations, PKI attacks, ...

Lately, with fancy names too: *BEAST, CRIME, TIME, Lucky 13, BREACH, POODLE, FREAK, Heartbleed, DROWN, ...*

Record Protocol

Message transport: [header | data] records (16K)

Encryption and integrity: after handshake completion

Compression: before encryption... not a good idea

Side-channel attacks (e.g., CRIME)

Subprotocols: allow for extensibility

TLS defines four core subprotocols:

handshake, change cipher spec, application data, alert

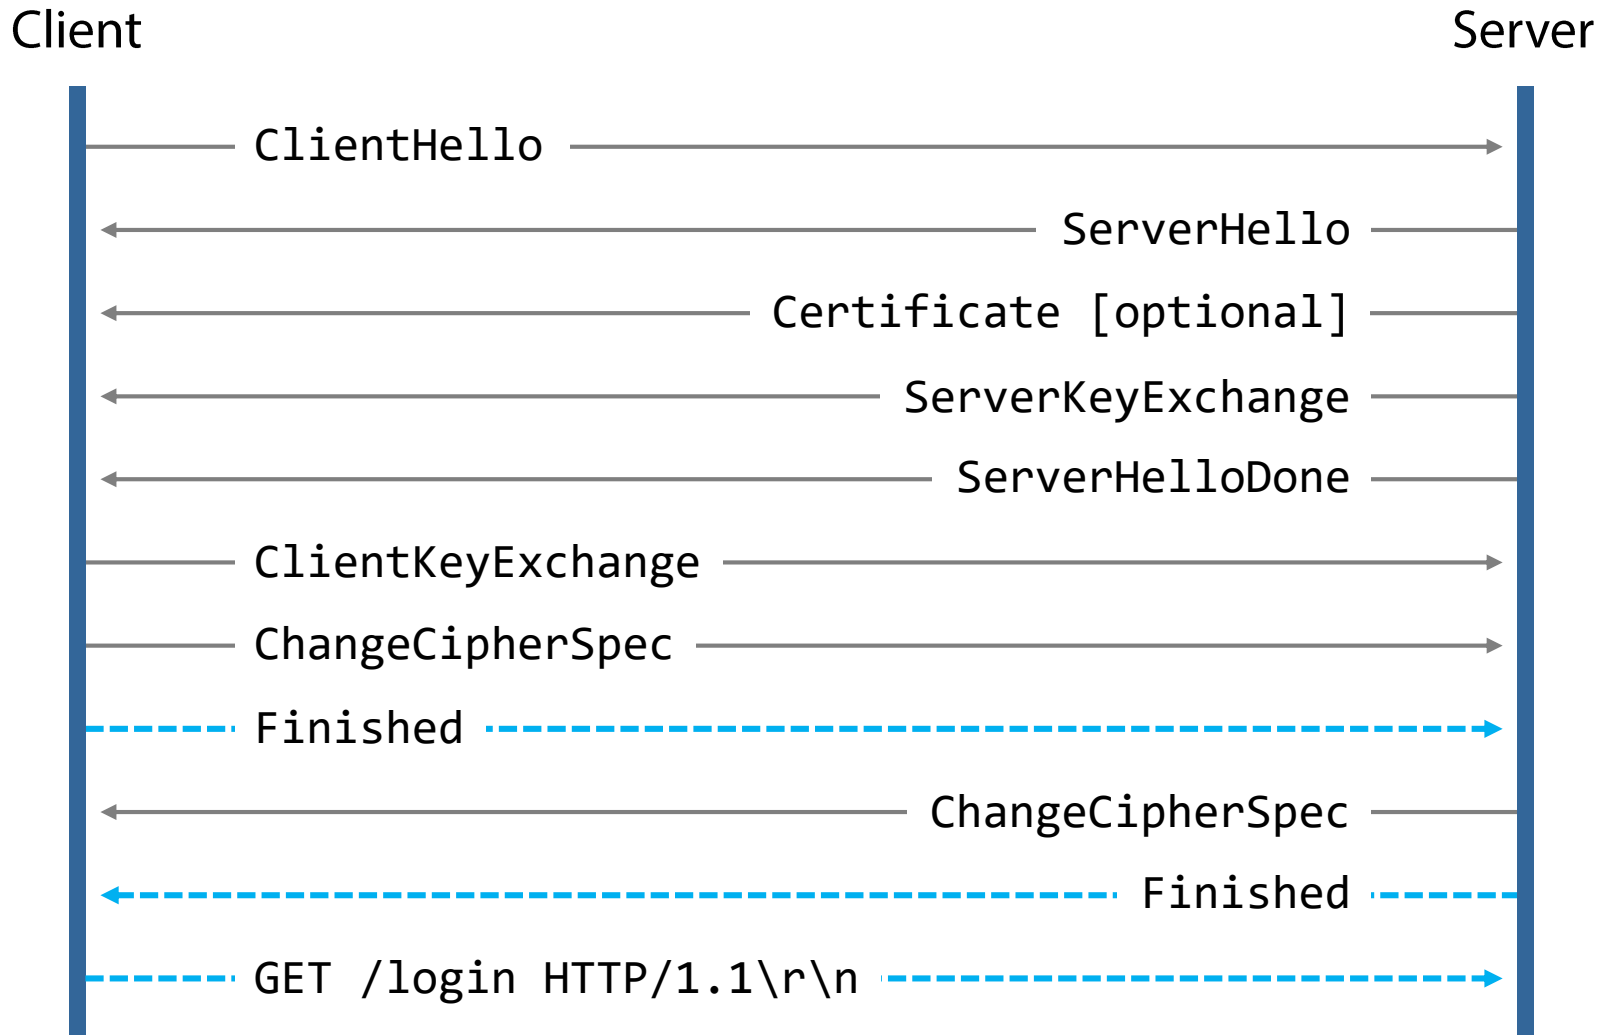

Handshake protocol

Negotiate session keys and crypto algorithms to be used

Authentication (server and optionally client)

Takes 6–10 messages, depending on features used

Basic SSL/TLS Handshake (Server Auth Only)

Cipher Suite Negotiation

ClientHello: *here are the cipher suites I support*

```
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256  
TLS_DHE_RSA_WITH_AES_128_GCM_SHA256  
TLS_RSA_WITH_AES_128_GCM_SHA256  
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA  
TLS_DHE_RSA_WITH_AES_128_CBC_SHA  
TLS_RSA_WITH_AES_128_CBC_SHA  
TLS_RSA_WITH_3DES_EDE_CBC_SHA  
TLS_RSA_WITH_RC4_128_SHA  
...
```

ServerHello: *let's use this one*

```
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
```

The server might not support the best of the client's suites

Offers some other version hoping that the client will accept it

Downgrade Attacks

Force a weaker cipher suite selection through MitM

SSL 2: no handshake integrity

SSL 3: protocol rollback protection (still breakable)

TLS 1.0 and on: additional protections

Due to server bugs and interoperability issues, browsers responded by voluntarily downgrading the protocol upon handshake failure

Retrying connection with lower SSL/TLS version

Attackers can exploit this by blocking initial handshake attempts

Or modify the client's list of supported clients (and include only weak ones)

SSL 3.0 is now completely removed by most browsers

TLS/SSL support history of web browsers

Browser	Version	Platforms	SSL protocols		TLS protocols			Certificate Support			Vulnerabilities fixed ^[n 1]					Protocol selection by user ^[n 2]

Session Resumption

Full handshake: 6-10 messages and two network round-trips

Along with CPU-intensive crypto operations, cert validation, ...

Avoid re-negotiation by remembering security parameters

Server assigns and sends a unique session ID as part of ServerHello

In future connections, the client sends the session ID to resume the session

Alternative: *session tickets* (all state is kept at client)

Server (and Client) Authentication

After handshake completion, the client knows it can “trust” the information in the server’s certificate

Assuming it trusts the issuing CA

SSL/TLS certs are based on the X.509 PKI standard

How is the certificate associated with the server?

Common Name (CN): server’s hostname

Similar process for authenticating clients

Highly-secure web services, some VPN services, ...

Most common: username+password over TLS connection

Certificate Fields

Version: v1 (basic), v2 (additional fields), v3 (extensions)

Serial Number: high-entropy integer

Signature Algorithm: encryption and hash algorithm used to sign the cert

Issuer: complex field that contains the *distinguished name (DN)* of the certificate issuer

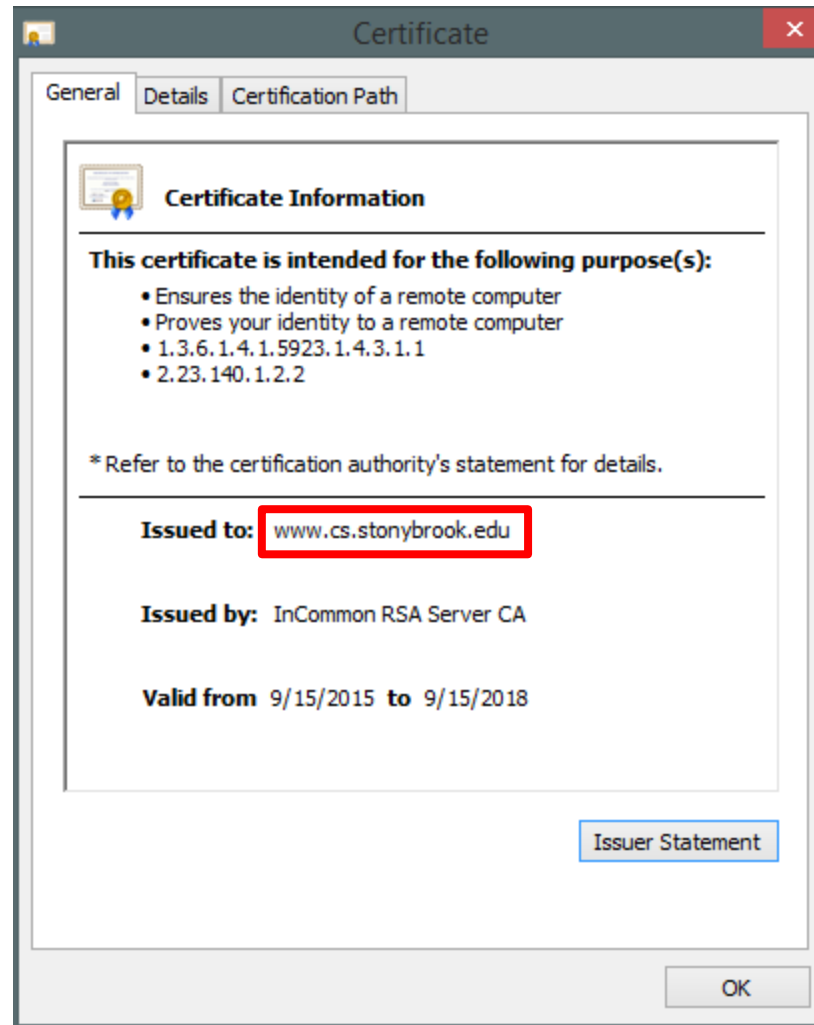

Validity: starting and ending date of validity period

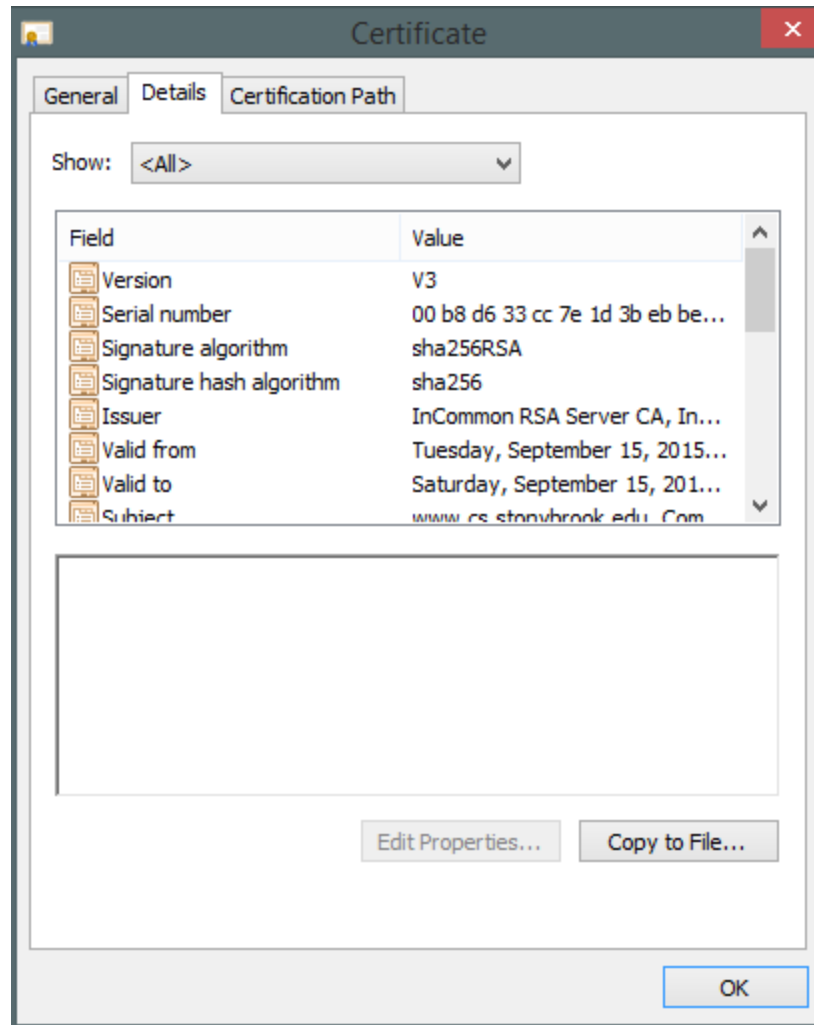

Subject: DN of the of the entity associated with the public key for which the certificate is issued

Deprecated in favor of the Subject Alternative Name (SAN) extension:
DNS name, IP address, or URI (also supports binding to multiple identities)

Public Key: The subject's public key

Signature

Certificate Chains

Trust anchors: systems are pre-configured with ~200 trusted root certificates

System/public store: used by OS, browsers, ...

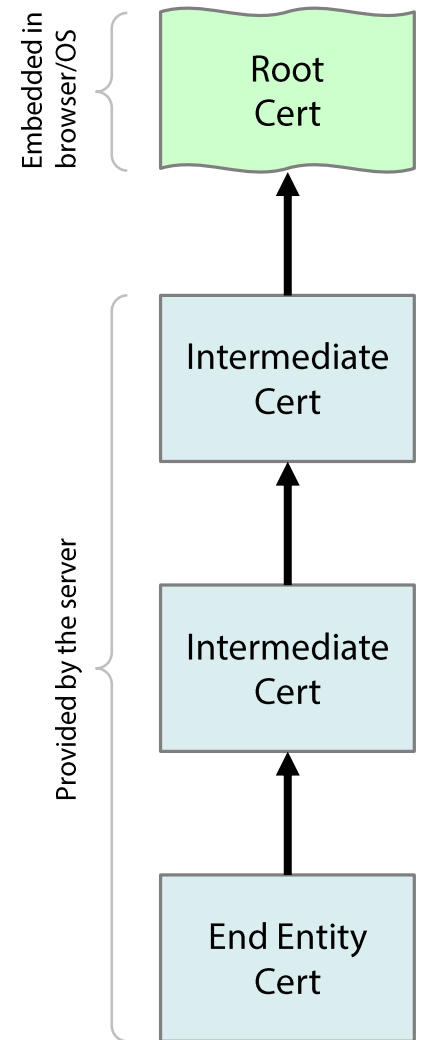

More can be added in the local/private cert store: vendor-specific certs, MitM certs for content inspection filters/AVs, ...

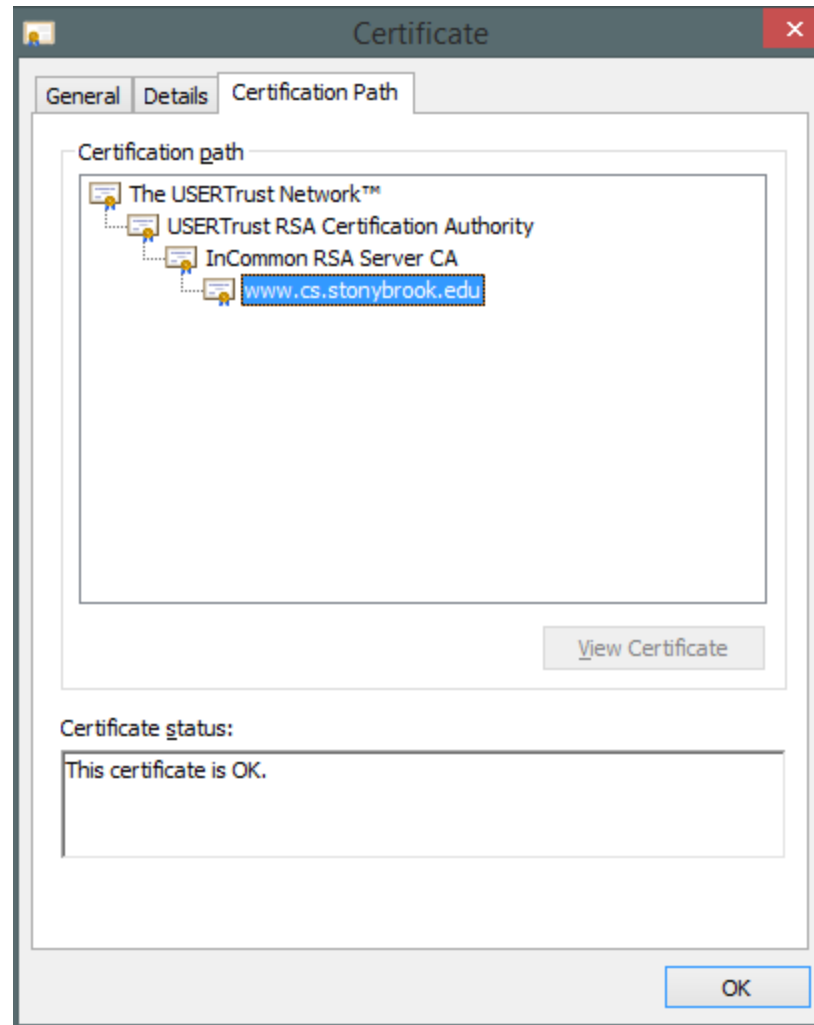

Server provides a *chain* of certificates

A certificate from an intermediate CA is trusted if there is a valid chain of trust all the way back to a trusted root CA

Any certificate authority can issue and sign certificates for any subject

The system is only as secure as the weakest certificate authority...

HTTPS

Most common use of SSL/TLS

Still, the majority of web traffic remains unencrypted...

Crypto is expensive, needs more CPU cycles

Not a big deal these days (native hardware support)

Mixed content: Ad networks, mashups, ...

Stop using them! ...easier said than done (lost revenue, increased development time)

Incentives: Google rewards HTTPS sites with higher ranking

Virtual Hosting: initially incompatible

Not anymore: solved as of TLS 1.1 through the Server Name Indication (SNI) extension → what about IE6 users?

Needs expertise and certs cost \$\$\$\$

Not anymore: letsencrypt.org

Browser Security Indicators

Convey information about the security of a page

Locks, shields, keys, green bars...

“This page was fetched using SSL”  <https://>

Page content was not viewed or altered by a network adversary
Certificate is valid (e.g. not expired), issued by a CA trusted by the browser, and the subject name matches the URL's domain

“This page uses an invalid certificate”  ~~<https://>~~

“Parts of the page are not encrypted”  <https://>

“The legal entity operating this web site is known”

Extended Validation (EV) certificates  [Square, Inc. \[US\] https://squareup.com](https://squareup.com)

The Irony...

Secure HTTPS		
HTTP		
HTTPS with minor errors		
Broken HTTPS		

} Basically the same in terms of security

Reflects better the security state of the page

Non-HTTPS traffic is a vulnerability!

MitM/MotS attacks on the HTTP part are trivial

Fewer security states for users to remember

SSL stripping

Browsing sessions often start with a plain HTTP page

Web sites switch to HTTPS only for login or checkout

Example: Facebook in 2010 (optional full HTTPS in 2011, on by default in 2013)

Users type addresses without specifying "https://"

Browser connects over HTTP → site may redirect to HTTPS

SSLstrip [Moxie Marlinspike, Black Hat DC 2009]

MitM attack to prevent redirection to HTTPS

Watch for HTTPS links and redirects and map them to HTTP links

...or homoglyph-similar *valid* HTTPS links:

<https://www.bank.com.attacker.com>

SSL stripping

Location: **http**://...

<form action="**http**://...">

Location: **https**://...

<form action="**https**://...">

Missing lock icon, but who is going to notice?

HSTS (HTTP Strict Transport Security)

Defense against SSL stripping and other issues

Convert any insecure links (**http://**) into secure links (**https://**) *before* accessing a resource

Treat all errors (e.g., invalid certificate, mixed content) as fatal: do not allow users to access the web application

A server implements an HSTS policy by supplying an extra HTTP header

```
Strict-Transport-Security: max-age=31536000
```

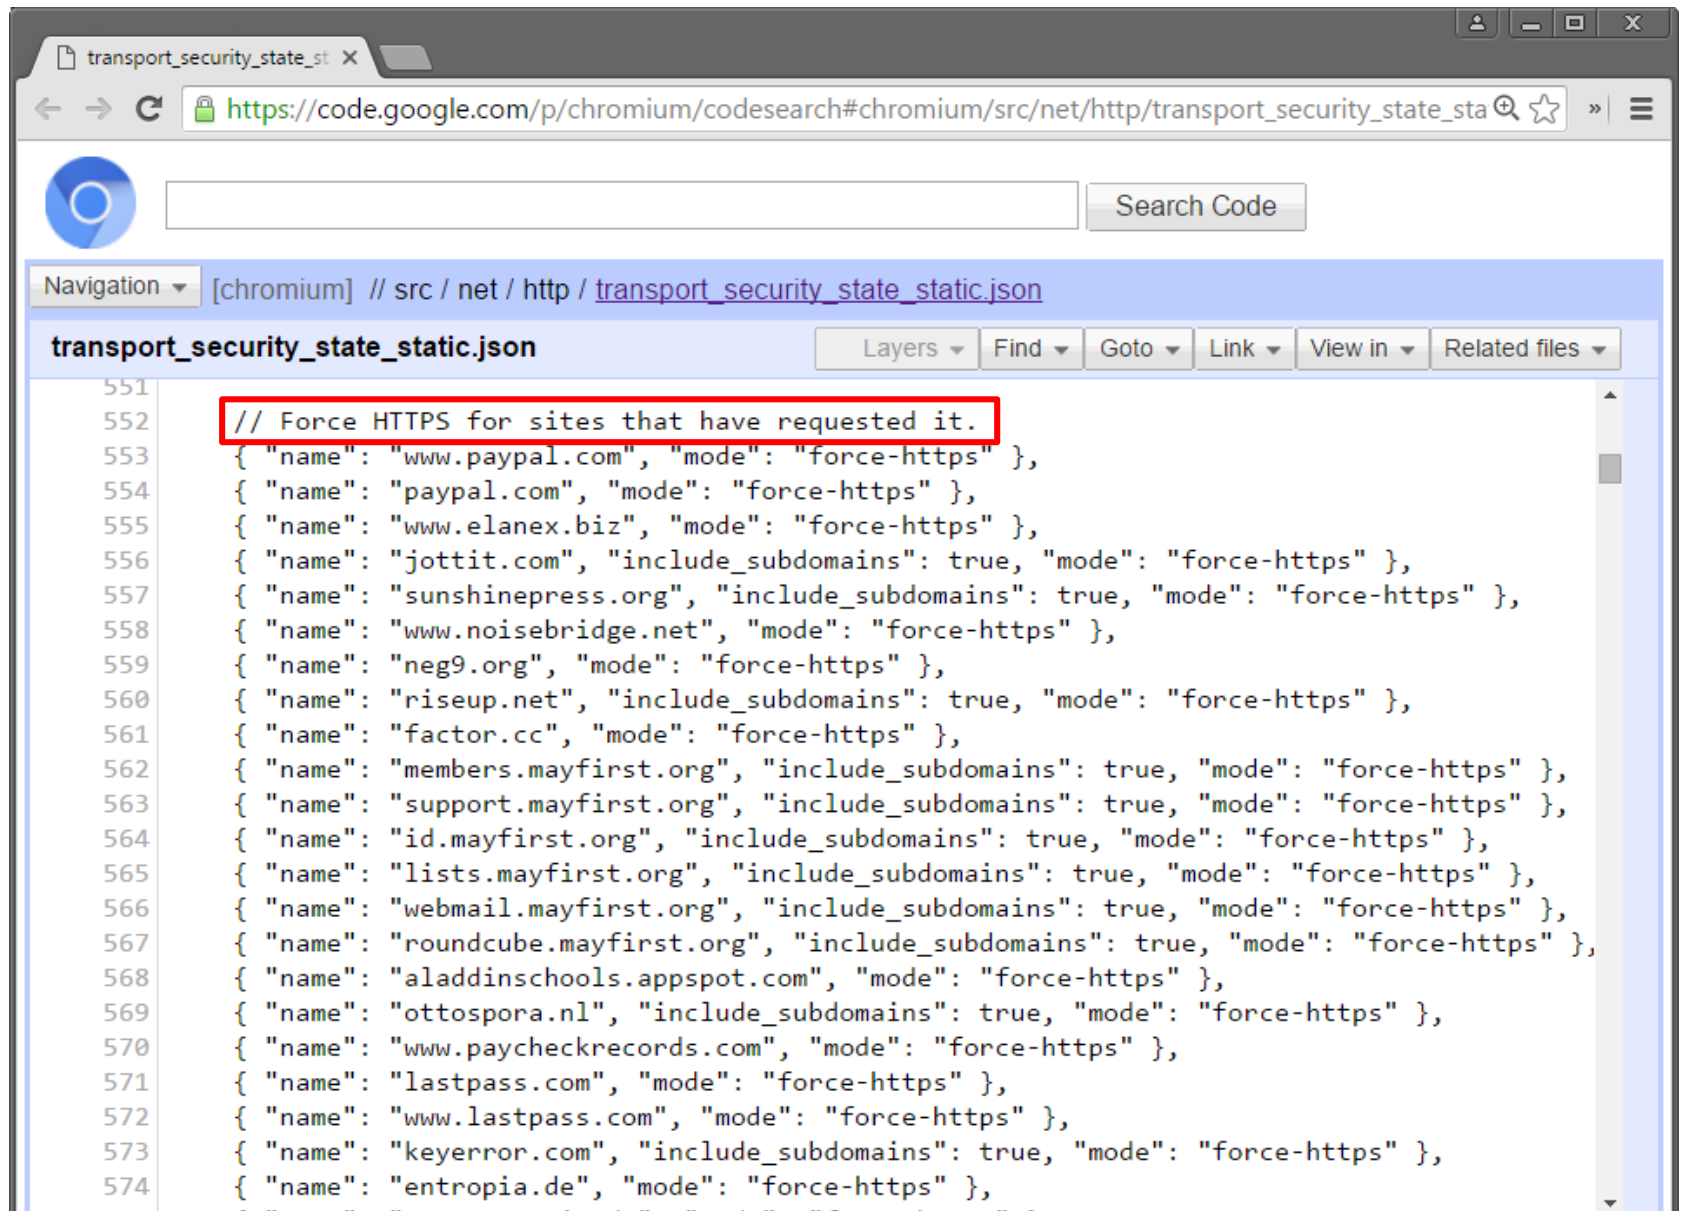

“Use only HTTPS for future requests to this domain for the next year”

An instance of *trust on first use (TOFU)*

The initial request *remains unprotected* if sent over HTTP

HSTS preloading: browser comes with a list of known HSTS sites

HSTS Preloading

```
551
552 // Force HTTPS for sites that have requested it.
553 { "name": "www.paypal.com", "mode": "force-https" },
554 { "name": "paypal.com", "mode": "force-https" },

MitM is Still Possible...

Rogue certificates

Most governments have a trusted root CA planted in our systems
Attackers may break into CAs and forge certificates

Pre-planted/generated certificates

Default static keys: Lenovo, Dell, anti-malware software, ...

Low entropy during key generation: repeated or factorable keys

Self-signed certificates

If desperate... will trigger browser warning

Exploitation of certificate validation flaws

Programming errors while checking date, hostname, ...

StartSSL suspends services after security breach

StartSSL has suspended issuance of digital certificates and related services following a security breach on 15 June. A trademark of Eddy Nigg's StartCom, the StartSSL certificate authority is well known for offering free domain validated SSL certificates, but also sells organisation and extended validation certificates.

More than 25 thousand websites in Netcraft's SSL survey use certificates issued by StartSSL. These are recognised by Internet Explorer, Firefox, Chrome and other mainstream browsers.

StartSSL is not alone in offering free certificates. AffirmTrust recently trumped StartSSL's one-year

certificates with its own offer of free three-year domain validated SSL certificates. Coincidentally, AffirmTrust announced its launch [on the same day](#) as the StartSSL security breach.

StartSSL is also not the only certificate authority to come under attack this year. In March, Comodo came [under attack](#) through three of its resellers. By compromising a [GlobalTrust](#) website, the so-called *ComodoHacker* managed to fraudulently issue several valid certificates, including ones for the login pages of Yahoo and Skype. These certificates were subsequently revoked and browser software was updated to explicitly

Trustwave to escape 'death penalty' for SSL skeleton key

Moz likely to spare certificate-confession biz same fate as DigiNotar

14 Feb 2012 at 09:28, John Leyden

12

10

Analysis Trustwave's admission that it issued a digital "skeleton key" that allowed an unnamed private biz to spy on SSL-encrypted connections within its corporate network has sparked a fiery debate about trust on the internet.

Trustwave, an SSL certificate authority, confessed to supplying a subordinate root certificate as part of an information security product that allowed a customer to monitor employees' web communications - even if the staffers relied on HTTPS. Trustwave said the man-in-the-middle (MitM) gear was designed both to be tamper-proof and to work only within its unnamed client's compound. Despite these precautions, Trustwave now admits that the whole approach was misconceived and would not be repeated. In addition, it revoked the offending certificate.

Trustwave came clean without the need for pressure beforehand. Even so its action have split security experts and prompted calls on Mozilla's Bugzilla security list to remove the Trustwave root certificate

HPKP (HTTP Public Key Pinning)

Prevent certificate forgery: strong form of web site authentication

Browser knows the *valid* public keys of a particular website

If a seemingly valid chain does not include at least one known pinned key, cert is rejected → not issued in accordance with the site operator's expectations

Doesn't apply for *private* root certificates

Would break preconfigured proxies, anti-malware, content filters, ...

Many incidents involving rogue certificates were discovered after browsers started rolling out pinning

Similar deployment as HSTS

TOFU: HTTP response header

Built-in pins in browsers

HSTS

capturing events (70)

HSTS is HTTPS Strict Transport Security: a way for sites to elect to always use HTTPS. See <http://dev.chromium.org/sts>.

Google Security Blog

The latest news and insights from Google on security and safety on the Internet

Enhancing digital certificate security

January 3, 2013

Posted by Adam Langley, Software Engineer

Late on December 24, **Chrome detected and blocked an unauthorized digital certificate for the "*.google.com" domain.** We investigated immediately and found the certificate was issued by an **intermediate certificate authority (CA)** linking back to TURKTRUST, a Turkish certificate authority. Intermediate CA certificates carry the full authority of the CA, so anyone who has one can use it to create a certificate for any website they wish to impersonate.

In response, we updated Chrome's certificate revocation metadata on

Google

google.com/+google

News and updates on Google's products, technology and more

Certificate Revocation

Mechanism to allow revocation of compromised or no longer needed certificates

Certificate revocation list (CRL)

List of all serial numbers belonging to revoked certificates that have not yet expired

Main problem: lists tend to be large, making real-time lookups slow

Can the attacker block connectivity to the status server?

Online Certificate Status Protocol (OCSP)

Obtain the revocation status of a *single* certificate → faster

But performance and privacy issues still remain

OCSP stapling: server embeds OCSP response directly into the TLS handshake
