• The Character Class
• Designing Classes
Immutable Objects and Classes

- **Immutable object**: the contents of an object cannot be changed once the object is created
- its class is called an **immutable class**
  - Example immutable class: no set method in the Circle class:
    ```java
    public class Circle{
      private double radius;
      public Circle() { }
      public Circle(double radius) {
        this.radius = radius;
      }
      public double getRadius() {
        return radius;
      }
    }
    ```
  - radius is private and cannot be changed without a set method
What Class is Immutable?

• A class with all private data fields and without mutators is not necessarily immutable!

• An *immutable class*:
  1. It must mark all data fields *private*!
  2. Provide no mutator (set) methods!
  3. Provide no accessor methods that would return a reference to a mutable data field object!
Example mutable

```java
public class Student {
    private int id;
    private BirthDate birthDate;
    public Student(int ssn, int year, int month, int day) {
        id = ssn;
        birthDate =
            new BirthDate(year, month, day);
    }
    public int getId() {
        return id;
    }
    public BirthDate getBirthDate() { return birthDate; }
}

public class BirthDate {
    private int year;
    private int month;
    private int day;
    public BirthDate(int newYear, int newMonth, int newDay) {
        year = newYear;
        month = newMonth;
        day = newDay;
    }
    public void setYear(int newYear) {
        year = newYear;
    }
    public int getYear() {
        return year;
    }
}

public class Test {
    public static void main(String[] args) {
        Student student = new Student(111223333, 1998, 1, 1);
        student.getBirthDate().setYear(2050);
        // Now the student birth year is changed:
        System.out.println(student.getBirthDate().getYear()); // 2050
    }
}
```

(c) Pearson Education, Inc. & Paul Fodor (CS Stony Brook)
Scope of Variables

- The scope of a local variable starts from its declaration and continues to the end of the block that contains the variable.
  - Also a local variable must be initialized explicitly before it can be used.

vs.

- Data Field Variables can be declared anywhere inside a class.
  - The scope of instance and static variables is the entire class!
  - Initialized with default values.
The *this* Keyword

- The *this* keyword is the name of a reference that refers to an object itself.
- Common uses of the *this* keyword:
  1. Reference a class’s “*hidden*” data fields.
  2. To enable a constructor to *invoke* another constructor of the same class as the first statement in the constructor.
Reference the Hidden Data Fields

```java
public class Foo {
    private int i = 5;
    private static double k = 0;
    
    void setI(int i) {
        this.i = i;
    }
    
    static void setK(double k) {
        Foo.k = k;
    }
}
```

Suppose that f1 and f2 are two objects of Foo.

Invoking `f1.setI(10)` is to execute `this.i = 10`, where `this` refers f1.

Invoking `f2.setI(45)` is to execute `this.i = 45`, where `this` refers f2.
public class Circle {
  private double radius;

  public Circle(double radius) {
    this.radius = radius;
  }

  public Circle() {
    this(1.0);
  }

  public double getArea() {
    return this.radius * this.radius * Math.PI;
  }
}

Every instance variable belongs to an instance represented by this, which is normally omitted.
**Class Abstraction** = separate class implementation from the use of the class (API)

- The creator of the class provides a description of the class and let the user know how the class can be used.
- The user does not need to know how the class is implemented: it is *encapsulated* (private fields and only the public API is used).

Class implementation is like a black box hidden from the clients

- Class
- Class Contract (Signatures of public methods and public constants)
- Clients use the class through the contract of the class
### Designing the Loan Class

<table>
<thead>
<tr>
<th>Loan</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-annualInterestRate: double</td>
<td>The annual interest rate of the loan (default: 2.5).</td>
</tr>
<tr>
<td>-numberOfYears: int</td>
<td>The number of years for the loan (default: 1).</td>
</tr>
<tr>
<td>-loanAmount: double</td>
<td>The loan amount (default: 1000).</td>
</tr>
<tr>
<td>-loanDate: Date</td>
<td>The date this loan was created.</td>
</tr>
<tr>
<td>+Loan()</td>
<td>Constructs a default Loan object.</td>
</tr>
<tr>
<td>+Loan(annualInterestRate: double, numberOfYears: int, loanAmount: double)</td>
<td>Constructs a loan with specified interest rate, years, and loan amount.</td>
</tr>
<tr>
<td>+getAnnualInterestRate(): double</td>
<td>Returns the annual interest rate of this loan.</td>
</tr>
<tr>
<td>+getNumberOfYears(): int</td>
<td>Returns the number of the years of this loan.</td>
</tr>
<tr>
<td>+getLoanAmount(): double</td>
<td>Returns the amount of this loan.</td>
</tr>
<tr>
<td>+getLoanDate(): Date</td>
<td>Returns the date of the creation of this loan.</td>
</tr>
<tr>
<td>+setAnnualInterestRate( annualInterestRate: double): void</td>
<td>Sets a new annual interest rate to this loan.</td>
</tr>
<tr>
<td>+setNumberOfYears( numberOfYears: int): void</td>
<td>Sets a new number of years to this loan.</td>
</tr>
<tr>
<td>+setLoanAmount( loanAmount: double): void</td>
<td>Sets a new amount to this loan.</td>
</tr>
<tr>
<td>+getMonthlyPayment(): double</td>
<td>Returns the monthly payment of this loan.</td>
</tr>
<tr>
<td>+getTotalPayment(): double</td>
<td>Returns the total payment of this loan.</td>
</tr>
</tbody>
</table>
public class Loan {
    private double annualInterestRate;
    private int numberOfYears;
    private double loanAmount;
    private java.util.Date loanDate;
    public Loan() {
        this(2.5, 1, 1000);
    }
    public Loan(double annualInterestRate, int numberOfYears,
                double loanAmount) {
        this.annualInterestRate = annualInterestRate;
        this.numberOfYears = numberOfYears;
        this.loanAmount = loanAmount;
        loanDate = new java.util.Date();
    }
    public double getMonthlyPayment() {
        double monthlyInterestRate = annualInterestRate / 1200;
        double monthlyPayment = loanAmount * monthlyInterestRate / (1 -
            (Math.pow(1 / (1 + monthlyInterestRate), numberOfYears * 12)));
        return monthlyPayment;
    }
    public double getTotalPayment() {
        double totalPayment = getMonthlyPayment() * numberOfYears * 12;
        return totalPayment;
    }
    ...
The BMI Class

<table>
<thead>
<tr>
<th>BMI</th>
<th>The get methods for these data fields are provided in the class, but omitted in the UML diagram for brevity.</th>
</tr>
</thead>
<tbody>
<tr>
<td>-name: String</td>
<td>The name of the person.</td>
</tr>
<tr>
<td>-age: int</td>
<td>The age of the person.</td>
</tr>
<tr>
<td>-weight: double</td>
<td>The weight of the person in pounds.</td>
</tr>
<tr>
<td>-height: double</td>
<td>The height of the person in inches.</td>
</tr>
<tr>
<td>+BMI(name: String, age: int, weight: double, height: double)</td>
<td>Creates a BMI object with the specified name, age, weight, and height.</td>
</tr>
<tr>
<td>+BMI(name: String, weight: double, height: double)</td>
<td>Creates a BMI object with the specified name, weight, height, and a default age 20.</td>
</tr>
<tr>
<td>+getBMI(): double</td>
<td>Returns the BMI</td>
</tr>
<tr>
<td>+getStatus(): String</td>
<td>Returns the BMI status (e.g., normal, overweight, etc.)</td>
</tr>
</tbody>
</table>
public class BMI {
  private String name;
  private int age;
  private double weight; // in pounds
  private double height; // in inches
  public static final double KILOGRAMS_PER_POUND = 0.45359237;
  public static final double METERS_PER_INCH = 0.0254;
  public BMI(String name, int age, double weight, double height) {
    this.name = name; this.age = age; this.weight = weight; this.height = height;
  }
  public double getBMI() {
    double bmi = weight * KILOGRAMS_PER_POUND / ((height * METERS_PER_INCH) * (height * METERS_PER_INCH));
    return Math.round(bmi * 100) / 100.0;
  }
  public String getStatus() {
    double bmi = getBMI();
    if (bmi < 16) return "seriously underweight";
    else if (bmi < 18) return "underweight";
    else if (bmi < 24) return "normal weight";
    else if (bmi < 29) return "over weight";
    else if (bmi < 35) return "seriously over weight";
    else return "gravelly over weight";
  }
  public String getName() { return name; }
  public int getAge() { return age; }
  public double getWeight() { return weight; }
  public double getHeight() { return height; }
}
### Example: The Course Class

<table>
<thead>
<tr>
<th>Course</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>- name: String</td>
<td>The name of the course.</td>
</tr>
<tr>
<td>- students: String[]</td>
<td>The students who take the course.</td>
</tr>
<tr>
<td>- numberOfStudents: int</td>
<td>The number of students (default: 0).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ Course(name: String)</td>
<td>Creates a Course with the specified name.</td>
</tr>
<tr>
<td>+ getName(): String</td>
<td>Returns the course name.</td>
</tr>
<tr>
<td>+ addStudent(student: String): void</td>
<td>Adds a new student to the course list.</td>
</tr>
<tr>
<td>+ getStudents(): String[]</td>
<td>Returns the students for the course.</td>
</tr>
<tr>
<td>+ getNumberOfStudents(): int</td>
<td>Returns the number of students for the course.</td>
</tr>
</tbody>
</table>
public class Course {
    private String courseName;
    private String[] students = new String[100];
    private int numberOfStudents;
    public Course(String courseName) {
        this.courseName = courseName;
    }
    public void addStudent(String student) {
        if (numberOfStudents >= students.length) {
            String[] temp = new String[students.length * 2];
            System.arraycopy(students, 0, temp, 0, students.length);
            students = temp;
        }
        students[numberOfStudents++] = student;
    }
    public String[] getStudents() {
        return students;
    }
    public int getNumberOfStudents() {
        return numberOfStudents;
    }
    public String getCourseName() {
        return courseName;
    }
}
**Example: The **StackOfIntegers** Class**

<table>
<thead>
<tr>
<th>StackOfIntegers</th>
<th>An array to store integers in the stack.</th>
</tr>
</thead>
<tbody>
<tr>
<td>-elements: int[]</td>
<td>The number of integers in the stack.</td>
</tr>
<tr>
<td>-size: int</td>
<td>Constructs an empty stack with a default capacity of 16.</td>
</tr>
<tr>
<td>+StackOfIntegers()</td>
<td>Constructs an empty stack with a specified capacity.</td>
</tr>
<tr>
<td>+StackOfIntegers(capacity: int)</td>
<td>Returns true if the stack is empty.</td>
</tr>
<tr>
<td>+empty(): boolean</td>
<td>Returns the integer at the top of the stack without removing it from the stack.</td>
</tr>
<tr>
<td>+peek(): int</td>
<td>Stores an integer into the top of the stack.</td>
</tr>
<tr>
<td>+push(value: int): int</td>
<td>Removes the integer at the top of the stack and returns it.</td>
</tr>
<tr>
<td>+pop(): int</td>
<td>Returns the number of elements in the stack.</td>
</tr>
<tr>
<td>+getSize(): int</td>
<td></td>
</tr>
</tbody>
</table>

(c) Pearson Education, Inc. & Paul Fodor (CS Stony Brook)
Designing the **StackOfIntegers** Class

Data1 → Data2 → Data3

Data3 → Data2 → Data1

Data1 → Data2 → Data3

Data1 → Data2 → Data3
Implementing `StackOfIntegers` Class

- `elements[capacity - 1]`
- `elements[size-1]`
- `elements[1]`
- `elements[0]`
- `top`
- `bottom`
- `capacity`
- `size`
public class StackOfIntegers {
    private int[] elements;
    private int size;
    public static final int DEFAULT_CAPACITY = 16;
    public StackOfIntegers() {
        this(DEFAULT_CAPACITY);
    }
    public StackOfIntegers(int capacity) {
        elements = new int[capacity];
    }
    public void push(int value) {
        if (size >= elements.length) {
            int[] temp = new int[elements.length * 2];
            System.arraycopy(elements, 0, temp, 0, elements.length);
            elements = temp;
        }
        elements[size++] = value;
    }
    public int pop() {
        return elements[--size];
    }
    public int peek() {
        return elements[size - 1];
    }
    public int getSize() {
        return size;
    }
}
The String class in detail

- Remember the String class discussed at the beginning of the semester?

- Constructing Strings:

  ```java
  String newString = new String(stringLiteral);
  ```

- Example:

  ```java
  String message = new String("Welcome to Java");
  ```

- Since strings are used frequently, Java provides a shorthand initializer for creating a string:

  ```java
  String message = "Welcome to Java";
  // an Interned String
  ```
Strings Are Immutable

- A String object is immutable; its contents cannot be changed.

```java
String s = "Java";
s = "HTML";
```

After executing `String s = "Java";`

```
: String
String object for "Java"

Contents cannot be changed
```

After executing `s = "HTML";`

```
: String
String object for "Java"

This string object is now unreferenced

: String
String object for "HTML"
```
**Interned Strings**

- *String interning* is a method of storing **only one copy** of each distinct compile-time constant/explicit string in the source code stored in a string intern pool (e.g., `s1` and `s3`).

- If we use the `new` operator, then a new object is created in heap (e.g., `s2`).

```java
String s1 = "Welcome to Java";
String s2 = new String("Welcome to Java");
String s3 = "Welcome to Java";

System.out.println("s1 == s2 is " + (s1 == s2));
System.out.println("s1 == s3 is " + (s1 == s3));
```

- **displays:** `s1 == s3` is **true**
- `s1 == s2` is **false**
The String Class methods

- Compare strings (equals, compareTo)
- Obtaining String length
- Retrieving Individual Characters in a string
- String Concatenation (concat)
- Substrings (substring(index), substring(start, end))
- Finding a Character or a Substring in a String
- Matching, Replacing and Splitting by Patterns
- Converting Characters and Numeric Values to Strings
- Command-Line Parameters
String Comparisons

- `equals(Object object)`:  
  
  ```java
  String s1 = new String("Welcome");
  String s2 = "Welcome";
  
  if (s1.equals(s2)) { // true
      // s1 and s2 have the same contents
  }
  
  if (s1 == s2) { // false
      // s1 and s2 have different references
  }
  ```
String Comparisons

- `equals(Object object)`:

```java
String s1 = "Welcome";
String s2 = "Welcome";

if (s1.equals(s2)) {  // true
    // s1 and s2 have the same contents
}

if (s1 == s2) {  // true
    // s1 and s2 have the same reference
}
```
String Comparisons

- `compareTo(Object object)`:

  ```java
  String s1 = new String("Welcome");
  String s2 = new String("Welcome");
  
  if (s1.compareTo(s2) > 0) {
      // s1 is greater than s2
  } else if (s1.compareTo(s2) == 0) {
      // s1 and s2 have the same contents
  } else {
      // s1 is less than s2
  }
  ```
# String Comparisons

<table>
<thead>
<tr>
<th>java.lang.String</th>
<th>Returns true if this string is equal to string s1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>+equals(s1: String): boolean</td>
<td>Returns true if this string is equal to string s1 case-insensitive.</td>
</tr>
<tr>
<td>+equalsIgnoreCase(s1: String): boolean</td>
<td>Returns an integer greater than 0, equal to 0, or less than 0 to indicate whether this string is greater than, equal to, or less than s1.</td>
</tr>
<tr>
<td>+compareTo(s1: String): int</td>
<td>Same as compareTo except that the comparison is case-insensitive.</td>
</tr>
<tr>
<td>+compareToIgnoreCase(s1: String): int</td>
<td>Returns true if the specified subregion of this string exactly matches the specified subregion in string s1.</td>
</tr>
<tr>
<td>+regionMatches(toffset: int, s1: String, offset: int, len: int): boolean</td>
<td>Same as the preceding method except that you can specify whether the match is case-sensitive.</td>
</tr>
<tr>
<td>+regionMatches(ignoreCase: boolean, toffset: int, s1: String, offset: int, len: int): boolean</td>
<td>Returns true if this string starts with the specified prefix.</td>
</tr>
<tr>
<td>+startsWith(prefix: String): boolean</td>
<td>Returns true if this string ends with the specified suffix.</td>
</tr>
<tr>
<td>+endsWith(suffix: String): boolean</td>
<td></td>
</tr>
</tbody>
</table>
## String Length, Characters, and Combining Strings

<table>
<thead>
<tr>
<th>java.lang.String</th>
</tr>
</thead>
<tbody>
<tr>
<td>+length(): int</td>
</tr>
<tr>
<td>+charAt(index: int): char</td>
</tr>
<tr>
<td>+concat(s1: String): String</td>
</tr>
</tbody>
</table>

- `+length()`: int
  Returns the number of characters in this string.

- `+charAt(index: int): char`
  Returns the character at the specified index from this string.

- `+concat(s1: String): String`
  Returns a new string that concatenate this string with string s1.
Retrieving Individual Characters in a String

- Use `message.charAt(index) → char`
- Index starts from 0

Indices: 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14

- `message.charAt(0)`
- `message.charAt(14)`
- `message.length()` is 15
- `message.charAt(14)`
## Extracting Substrings

<table>
<thead>
<tr>
<th>java.lang.String</th>
</tr>
</thead>
<tbody>
<tr>
<td>+subString(beginIndex: int): String</td>
</tr>
<tr>
<td>+subString(beginIndex: int, endIndex: int): String</td>
</tr>
</tbody>
</table>

Returns this string’s substring that begins with the character at the specified beginIndex and extends to the end of the string.

Returns this string’s substring that begins at the specified beginIndex and extends to the character at index endIndex – 1. Note that the character at endIndex is not part of the substring.
String s1 = "Welcome to Java";
String s2 = s1.substring(0, 11) + "HTML";

s2 will be "Welcome to HTML"
Finding a Character or a Substring in a String

<table>
<thead>
<tr>
<th>java.lang.String</th>
</tr>
</thead>
<tbody>
<tr>
<td>+indexOf(ch: char): int</td>
</tr>
<tr>
<td>+indexOf(ch: char, fromIndex: int): int</td>
</tr>
<tr>
<td>+indexOf(s: String): int</td>
</tr>
<tr>
<td>+indexOf(s: String, fromIndex: int): int</td>
</tr>
<tr>
<td>+lastIndexOf(ch: int): int</td>
</tr>
<tr>
<td>+lastIndexOf(ch: int, fromIndex: int): int</td>
</tr>
<tr>
<td>+lastIndexOf(s: String): int</td>
</tr>
<tr>
<td>+lastIndexOf(s: String, fromIndex: int): int</td>
</tr>
</tbody>
</table>

Returns the index of the first occurrence of ch in the string. Returns -1 if not matched.

Returns the index of the first occurrence of ch after fromIndex in the string. Returns -1 if not matched.

Returns the index of the first occurrence of string s in this string. Returns -1 if not matched.

Returns the index of the first occurrence of string s in this string after fromIndex. Returns -1 if not matched.

Returns the index of the last occurrence of ch in the string. Returns -1 if not matched.

Returns the index of the last occurrence of ch before fromIndex.

Returns the index of the last occurrence of string s. Returns -1 if not matched.

Returns the index of the last occurrence of string s before fromIndex. Returns -1 if not matched.
### Finding a Character or a Substring in a String

<table>
<thead>
<tr>
<th>Indices</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
<th>13</th>
<th>14</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>W</td>
<td>e</td>
<td>l</td>
<td>c</td>
<td>o</td>
<td>m</td>
<td>e</td>
<td></td>
<td>t</td>
<td>o</td>
<td>J</td>
<td>a</td>
<td>v</td>
<td>a</td>
<td></td>
</tr>
</tbody>
</table>

"Welcome to Java".indexOf('W') returns 0.

"Welcome to Java".indexOf('x') returns -1.

"Welcome to Java".indexOf('o', 5) returns 9.

"Welcome to Java".indexOf("come") returns 3.

"Welcome to Java".indexOf("Java", 5) returns 11.

"Welcome to Java".indexOf("java", 5) returns -1.

"Welcome to Java".lastIndexOf('a') returns 14.
Converting, Replacing, and Splitting Strings

<table>
<thead>
<tr>
<th>java.lang.String</th>
</tr>
</thead>
<tbody>
<tr>
<td>+toLowerCase(): String</td>
</tr>
<tr>
<td>+toUpperCase(): String</td>
</tr>
<tr>
<td>+trim(): String</td>
</tr>
<tr>
<td>+replace(oldChar: char, newChar: char): String</td>
</tr>
<tr>
<td>+replaceFirst(oldString: String, newString: String): String</td>
</tr>
<tr>
<td>+replaceAll(oldString: String, newString: String): String</td>
</tr>
<tr>
<td>+split(delimiter: String): String[]</td>
</tr>
</tbody>
</table>

- Returns a new string with all characters converted to lowercase.
- Returns a new string with all characters converted to uppercase.
- Returns a new string with blank characters trimmed on both sides.
- Returns a new string that replaces all matching character in this string with the new character.
- Returns a new string that replaces the first matching substring in this string with the new substring.
- Returns a new string that replace all matching substrings in this string with the new substring.
- Returns an array of strings consisting of the substrings split by the delimiter.
Examples

"Welcome".toLowerCase() returns a new string, "welcome".
"Welcome".toUpperCase() returns a new string, "WELCOME".
"Welcome to Java".trim() returns a new string, "Welcome to Java".
"Welcome".replace('e', 'A') returns a new string, "WAlcomA".
"Welcome".replaceFirst("e", "AB") returns a new string, "WABlcome".
"Welcome".replaceAll("e", "AB") returns a new string, "WABlcomAB".
"Welcome".replaceAll("el", "AB") returns a new string, "WABcome".
Splitting a String

String[] tokens = "Java#HTML#Perl".split("#");
for(int i = 0; i < tokens.length; i++)
    System.out.println(tokens[i]);

displays

Java
HTML
Perl
Matching, Replacing and Splitting by Patterns

- The `replaceAll`, `replaceFirst`, `split` and `matches` methods can be used with a **regular expression** (a sequence of characters that specifies a search pattern)

  - Example: the following statement returns a new string that replaces $, ±, or # in "a+b$#c" by the string NNN.

```java
String s = "a+b$#c".replaceAll("[$+#]", "NNN");
System.out.println(s);
```

  Displays: aNNN NbNNNNNNNc

- The regular expression `[$+#]` specifies a pattern that matches $, ±, or #
### Matching, Replacing and Splitting by Patterns

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>matches(regex: String): boolean</code></td>
<td>Returns true if this string matches the pattern.</td>
</tr>
<tr>
<td><code>replaceAll(regex: String, replacement: String): String</code></td>
<td>Returns a new string that replaces all matching substrings with the replacement.</td>
</tr>
<tr>
<td><code>replaceFirst(regex: String, replacement: String): String</code></td>
<td>Returns a new string that replaces the first matching substring with the replacement.</td>
</tr>
<tr>
<td><code>split(regex: String): String[]</code></td>
<td>Returns an array of strings consisting of the substrings split by the matches.</td>
</tr>
</tbody>
</table>
Matching, Replacing and Splitting by Patterns

- The **matches** method tells whether or not a string matches a given regular expression.

  "Java is fun".matches("Java.*")

  true

Social security numbers is **xxx-xx-xxxx**, where x is a digit:

  ```
  [\d]{3}-[\d]{2}-[\d]{4}
  ```

An even number ends with digits **0, 2, 4, 6, or 8**:

  ```
  [\d]*[02468]
  ```

Telephone numbers (**xxx**) **xxx-xxxx**, where x is a digit and the first digit cannot be zero:

  ```
  ([1-9][\d]{2}) [\d]{3}-[\d]{4}
  ```

</tbody>
</table>
The following statement splits the string into an array of strings delimited by some punctuation marks:

```java
String[] tokens = "Java,C;C#.C++".split("[,:;.]"_digits
for (int i = 0; i < tokens.length; i++)
    System.out.println(tokens[i]);
```

Displays:

Java
C
C#
C++
Examples

String s = "Java Java Java".replaceAll("v\\w", "wi") ;
    // “Jawi Jawi Jawi”

String s2 = "Java Java Java".replaceFirst("v\\w", "wi") ;
    // “Jawi Java Java”

String[] s3 = "Java1HTML2Perl".split("\\d");
    // [“Java”, “HTML”, “Perl”]
class TestMain {
    public static void main(String[] args) {
        ...
    }
}

- We can run the program with:

java TestMain arg0 arg1 arg2 ... argn

or the EclipseIDE Run Configuration arguments

- In the main method, get the arguments args[0], args[1], ..., args[n] corresponds to arg0, arg1, ..., argn in the command line or the EclipseIDE Run Configuration arguments
public class Calculator {
    public static void main(String[] args) {
        if (args.length != 3) {
            System.out.println("Usage: java Calculator operand1 operator operand2");
            System.exit(0);
        }
        int result = 0;
        switch (args[1].charAt(0)) {
            case '+':
                result = Integer.parseInt(args[0]) + Integer.parseInt(args[2]);
                break;
            ...
        }
    }
}

javac Calculator.java
java Calculator 1 + 2 3
StringBuilder and StringBuffer

- The **StringBuilder/StringBuffer** classes are alternatives to the **String** class:
  - **StringBuilder/StringBuffer** can be used wherever a string is used
    - **StringBuilder** is synchronized i.e. thread safe. It means two threads can't call the methods of **StringBuffer** simultaneously.
    - **StringBuilder** is non-synchronized i.e. not thread safe. It means two threads can call the methods of StringBuilder simultaneously.
  - **StringBuilder/StringBuffer** is more flexible than **String**
    - You can **add**, **insert**, or **append** new contents into a string buffer, whereas the value of a **String** object is fixed once the string is created
StringBuilder Constructors

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+StringBuilder()</td>
<td>Constructs an empty string builder with capacity 16.</td>
</tr>
<tr>
<td>+StringBuilder(capacity: int)</td>
<td>Constructs a string builder with the specified capacity.</td>
</tr>
<tr>
<td>+StringBuilder(s: String)</td>
<td>Constructs a string builder with the specified string.</td>
</tr>
</tbody>
</table>
## Modifying StringBuilder(s)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>append(data: char[])</code>: StringBuilder</td>
<td>Appends a char array into this string builder.</td>
</tr>
<tr>
<td><code>append(data: char[], offset: int, len: int): StringBuilder</code></td>
<td>Appends a subarray in data into this string builder.</td>
</tr>
<tr>
<td><code>append(v: aPrimitiveType): StringBuilder</code></td>
<td>Appends a primitive type value as a string to this builder.</td>
</tr>
<tr>
<td><code>append(s: String): StringBuilder</code></td>
<td>Appends a string to this string builder.</td>
</tr>
<tr>
<td><code>delete(startIndex: int, endIndex: int): StringBuilder</code></td>
<td>Deletes characters from startIndex to endIndex.</td>
</tr>
<tr>
<td><code>deleteCharAt(index: int): StringBuilder</code></td>
<td>Deletes a character at the specified index.</td>
</tr>
<tr>
<td><code>insert(index: int, data: char[], offset: int, len: int): StringBuilder</code></td>
<td>Inserts a subarray of the data in the array to the builder at the specified index.</td>
</tr>
<tr>
<td><code>insert(offset: int, data: char[])</code>: StringBuilder</td>
<td>Inserts data into this builder at the position offset.</td>
</tr>
<tr>
<td><code>insert(offset: int, b: aPrimitiveType): StringBuilder</code></td>
<td>Inserts a value converted to a string into this builder.</td>
</tr>
<tr>
<td><code>insert(offset: int, s: String): StringBuilder</code></td>
<td>Inserts a string into this builder at the position offset.</td>
</tr>
<tr>
<td><code>replace(startIndex: int, endIndex: int, s: String): StringBuilder</code></td>
<td>Replaces the characters in this builder from startIndex to endIndex with the specified string.</td>
</tr>
<tr>
<td><code>reverse(): StringBuilder</code></td>
<td>Reverses the characters in the builder.</td>
</tr>
<tr>
<td><code>setCharAt(index: int, ch: char): void</code></td>
<td>Sets a new character at the specified index in this builder.</td>
</tr>
</tbody>
</table>
Modifying StringBuilder(s)

StringBuilder stringBuilder = new StringBuilder();
stringBuilder.append("Java");
stringBuilder.insert(2,"HTML and ");
stringBuilder.delete(3, 4);
stringBuilder.deleteCharAt(5);
stringBuilder.reverse();
stringBuilder.replace(4, 8, "HTML");
stringBuilder.setCharAt(0, 'w');
The **toString**, **capacity**, **length**, **setLength**, and **charAt** Methods

<table>
<thead>
<tr>
<th>java.lang.StringBuilder</th>
</tr>
</thead>
<tbody>
<tr>
<td>+toString(): String</td>
</tr>
<tr>
<td>+capacity(): int</td>
</tr>
<tr>
<td>+charAt(index: int): char</td>
</tr>
<tr>
<td>+length(): int</td>
</tr>
<tr>
<td>+setLength(newLength: int): void</td>
</tr>
<tr>
<td>+substring(startIndex: int): String</td>
</tr>
<tr>
<td>+substring(startIndex: int, endIndex: int): String</td>
</tr>
<tr>
<td>+trimToSize(): void</td>
</tr>
</tbody>
</table>

- Returns a string object from the string builder.
- Returns the capacity of this string builder.
- Returns the character at the specified index.
- Returns the number of characters in this builder.
- Sets a new length in this builder.
- Returns a substring starting at startIndex.
- Returns a substring from startIndex to endIndex-1.
- Reduces the storage size used for the string builder.
The **Character Class**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+Character(value: char)</code></td>
<td>Constructs a character object with char value</td>
</tr>
<tr>
<td><code>+charValue(): char</code></td>
<td>Returns the char value from this object</td>
</tr>
<tr>
<td><code>+compareTo(anotherCharacter: Character): int</code></td>
<td>Compares this character with another</td>
</tr>
<tr>
<td><code>+equals(anotherCharacter: Character): boolean</code></td>
<td>Returns true if this character equals to another</td>
</tr>
<tr>
<td><code>+isDigit(ch: char): boolean</code></td>
<td>Returns true if the specified character is a digit</td>
</tr>
<tr>
<td><code>+isLetter(ch: char): boolean</code></td>
<td>Returns true if the specified character is a letter</td>
</tr>
<tr>
<td><code>+isLetterOrDigit(ch: char): boolean</code></td>
<td>Returns true if the character is a letter or a digit</td>
</tr>
<tr>
<td><code>+isLowerCase(ch: char): boolean</code></td>
<td>Returns true if the character is a lowercase letter</td>
</tr>
<tr>
<td><code>+isUpperCase(ch: char): boolean</code></td>
<td>Returns true if the character is an uppercase letter</td>
</tr>
<tr>
<td><code>+toLowerCase(ch: char): char</code></td>
<td>Returns the lowercase of the specified character</td>
</tr>
<tr>
<td><code>+toUpperCase(ch: char): char</code></td>
<td>Returns the uppercase of the specified character</td>
</tr>
</tbody>
</table>
equals and compareTo

Character charObject = new Character('b');

charObject.equals(new Character('b'))
  returns true

charObject.equals(new Character('d'))
  returns false

charObject.compareTo(new Character('a'))
  returns 1

charObject.compareTo(new Character('b'))
  returns 0

charObject.compareTo(new Character('c'))
  returns -1

charObject.compareTo(new Character('d'))
  returns -2
Designing Classes

• Coherence: A class should describe a single entity

• Separating responsibilities: A single entity with too many responsibilities can be broken into several classes to separate responsibilities

• Reuse: Classes are designed for reuse!
Designing Classes

- Follow standard Java programming style and naming conventions:
  - Choose informative names for classes, data fields, and methods
  - Place the data declaration before the constructor, and place constructors before methods.
- Provide a public no-arg constructor and override the `equals` method and the `toString` method (returns a `String`) whenever possible
