http://www.cs.stonybrook.edu/~cse316
Structural Design Patterns

• Design patterns that ease the design by identifying a simple way to realize relationships between entities.
  • *Decorator pattern*: adds additional functionality to a class at runtime where subclassing would result in an exponential rise of new classes.
  • *Adapter pattern*: "adapts" one interface for a class into one that a client expects.
  • *Facade pattern*: creates a simplified interface of an existing interface to ease usage for common tasks.
  • *Flyweight pattern*: a high quantity of objects share a common properties object to save space.
  • *Bridge pattern*: decouples an abstraction from its implementation so that the two can vary independently.

Textbook: Head First Design Patterns
The Decorator Pattern

- Attaches additional responsibilities to an object using delegation
  - i.e. by decorating an object
- Decorators provide a flexible alternative to sub-classing for extending functionality
- How?
  - By wrapping an object in another object
- Works on the principle that classes should be open to extension but closed to modification
  - Allow classes to be easily extended to incorporate new behavior without modifying existing code
    - Designs that are resilient to change and flexible enough to take on new functionality to meet changing requirements
Starbuzz Coffee

Beverage is an abstract class, subclassed by all beverages offered in the coffee shop.

The `cost()` method is abstract; subclasses need to define their own implementation.

The `getDescription()` method is set in each subclass and holds a description of the beverage, like “Most Excellent Dark Roast”. The `getDescription()` method returns the description.

Each subclass implements `cost()` to return the cost of the beverage.
We want to represent whether or not each beverage has milk, mocha, whip, soy, etc.

The superclass `cost()` will calculate the costs for all of the condiments, while the overridden `cost()` in the subclasses will extend that functionality to include costs for that specific beverage type.

Each `cost()` method needs to compute the cost of the beverage and then add in the condiments by calling the superclass implementation of `cost()`.

Problem: this cannot change in the future. For Halloween, we want to add pumpkin spice. For Thanksgiving, we want to add cinnamon. For Christmas, …
We can use inheritance:

But it results in Class Explosion

Each cost method computes the cost of the coffee along with the other condiments in the order.
Decorator pattern

• We’ll start with a beverage and "decorate" it with the condiments at runtime.

• For example, if the customer wants a Dark Roast with Mocha and Whip, then we’ll:
  1. Take a DarkRoast object.
  2. Decorate it with a Mocha object.
  3. Decorate it with a Whip object.
  4. Call the cost() method and rely on delegation to add on the condiment costs.
Beverage acts as our abstract component class.

The four concrete components, one per coffee type.
abstract class Beverage {
    String description = "Unknown Beverage";
    public String getDescription() {
        return description;
    }
    public abstract double cost();
}

class Espresso extends Beverage {
    public Espresso() {
        description = "Espresso";
    }
    public double cost() {
        return 1.99;
    }
}

class DarkRoast extends Beverage {
    public DarkRoast() {
        description = "DarkRoast";
    }
    public double cost() {
        return 0.99;
    }
}

class HouseBlend extends Beverage {
    public HouseBlend() {
        description = "HouseBlend";
    }
    public double cost() {
        return 0.99;
    }
}
abstract class CondimentDecorator extends Beverage {
    public abstract String getDescription();
}

class Mocha extends CondimentDecorator {
    Beverage beverage;
    public Mocha(Beverage beverage) {
        this.beverage = beverage;
    }
    public String getDescription() {
        return beverage.getDescription() + ", Mocha";
    }
    public double cost() {
        return .20 + beverage.cost();
    }
}

class Whip extends CondimentDecorator {
    Beverage beverage;
    public Whip(Beverage beverage) {
        this.beverage = beverage;
    }
    public String getDescription() {
        return beverage.getDescription() + ", Whip";
    }
    public double cost() {
        return .10 + beverage.cost();
    }
}
class Soy extends CondimentDecorator {
    Beverage beverage;
    public Soy(Beverage beverage) {
        this.beverage = beverage;
    }
    public String getDescription() {
        return beverage.getDescription() + ', Soy';
    }
    public double cost() {
        return .15 + beverage.cost();
    }
}
public class StarbuzzCoffee {
    public static void main(String[] args) {
        Beverage beverage = new Espresso();
        System.out.println(beverage.getDescription() + " $" + beverage.cost());

        Beverage beverage2 = new DarkRoast();
        beverage2 = new Mocha(beverage2);
        beverage2 = new Mocha(beverage2);
        beverage2 = new Whip(beverage2);
        System.out.println(beverage2.getDescription() + " $" + beverage2.cost());

        Beverage beverage3 = new Mocha(new Whip(new HouseBlend()));
        System.out.println(beverage3.getDescription() + " $" + beverage3.cost());

        Beverage beverage4 = new Soy(new Mocha(new Whip(new HouseBlend())));
        System.out.println(beverage4.getDescription() + " $" + beverage4.cost());
    }
}
Java’s IO Library

LineNumberInputStream is also a concrete decorator. It adds the ability to count the line numbers as it reads data.

BufferedInputStream is a concrete decorator. BufferedInputStream adds behavior in two ways: it buffers input to improve performance, and also augments the interface with a new method readLine() for reading character-based input, a line at a time.

FileInputStream is the component that’s being decorated. The Java I/O library supplies several components, including FileInputStream, StringBufferInputStream, ByteArrayInputStream and a few others. All of these give us a base component from which to read bytes.

A text file for reading.
// Adoption in many GUI frameworks for scrollbars
public interface Window {
    public void draw(); // Draws the Window
    public String getDescription(); // Returns a description
}

// Extension of a simple Window without any scrollbars
class SimpleWindow implements Window {
    public void draw() {
        // Draw window
    }
    public String getDescription() {
        return "simple window";
    }
}

// abstract decorator class - it implements Window
abstract class WindowDecorator implements Window {
    protected Window windowToBeDecorated;
    public WindowDecorator (Window windowToBeDecorated) {
        this.windowToBeDecorated = windowToBeDecorated;
    }
    public void draw() {
        windowToBeDecorated.draw(); // Delegation
    }
}
public String getDescription() {
    return windowToBeDecorated.getDescription();  // Delegation
}

// The first concrete decorator - adds vertical scrollbar
class VerticalScrollBarDecorator extends WindowDecorator {
    public VerticalScrollBarDecorator(Window windowToBeDecorated) {
        super(windowToBeDecorated);
    }
    @Override
    public void draw() {
        super.draw();
        drawVerticalScrollBar();
    }
    private void drawVerticalScrollBar() {
        // Draw the vertical scrollbar
    }
    @Override
    public String getDescription() {
        return super.getDescription() + ", including vertical scrollbars";
    }
}
// The second concrete decorator – adds horizontal scrollbar
class HorizontalScrollBarDecorator extends WindowDecorator {
    public HorizontalScrollBarDecorator(Window windowToBeDecorated) {
        super(windowToBeDecorated);
    }
    @Override
    public void draw() {
        super.draw();
        drawHorizontalScrollBar();
    }
    private void drawHorizontalScrollBar() {
        // Draw the horizontal scrollbar
    }
    @Override
    public String getDescription() {
        return super.getDescription() + ", including horizontal scrollbars";
    }
}
The output of this program is "simple window, including vertical scrollbars, including horizontal scrollbars" (each decorator decorates the window description with a suffix).
Decorators override functionality

Textbook: Head First Design Patterns
Ever been to Europe, Asia or Australia?

- What are adapters?

The European wall outlet exposes one interface for getting power.

The adapter converts one interface into another.

The US laptop expects another interface.
The Adapter Pattern

- Converts the interface of a class into another interface a client expects
- Adapter lets classes work together that couldn’t otherwise because of incompatible interfaces
The Adapter Pattern

- Do you know what a driver is?

- Problem:
  - Existing system uses a driver through an interface
  - New hardware has a new different interface

- Solution:
  - Adapter can adapt differences

Device drivers.
Object oriented adapters

- You have an existing system
- You need to work a vendor library into the system
- The new vendor interface is different from the last vendor
- You really don’t want to change your existing system
- Solution: Make a class that adapts the new vendor interface into what the system uses.
Adapter Visualized

Your Existing System

Vendor Class

Their interface doesn’t match the one you’ve written your code against. This isn’t going to work!

Your Existing System

Adapter

Vendor Class

The adapter implements the interface your classes expect.

And talks to the vendor interface to service your requests.

Your Existing System

Adapter

Vendor Class

No code changes.

New code.

No code changes.
How do we do it?

- Existing system HAS-A OldInterface
- Adapter implements OldInterface and HAS-A NewInterface
- Existing system calls OldInterface methods on adapter, adapter forwards them to NewInterface implementations
What’s good about this?

- Decouple the client from the implemented interface
- If we expect the interface to change over time, the adapter encapsulates that change so that the client doesn’t have to be modified each time it needs to operate against a different interface.
public interface Duck {
    void quack();
    void walk();
}

public class MallardDuck implements Duck {
    @Override
    public void quack() {
        System.out.println("Quack... quack...");
    }
    @Override
    public void walk() {
        System.out.println("Walking duck ...");
    }
}

public class Main {
    public static void main(String[] args) {
        System.out.println("Duck: ");
        Duck duck = new MallardDuck();
        test(duck);
    }

    static void test(Duck duck) {
        duck.quack();
        duck.walk();
    }
}
public class Turkey {
    public void gobble() {
        System.out.println("Gobble ... gobble ...");
    }
    public void walk() {
        System.out.println("Walking turkey ...");
    }
}

public class TurkeyAdapter implements Duck {
    private Turkey turkey;
    public TurkeyAdapter(Turkey turkey) {
        this.turkey = turkey;
    }
    @Override
    public void quack() {
        turkey.gobble();
    }
    @Override
    public void walk() {
        turkey.walk();
    }
}

public class Main {
    public static void main(String[] args) {
        System.out.println("Fake duck (i.e., turkey): ");
        Duck x = new TurkeyAdapter(new Turkey());
        test(x);
    }
    static void test(Duck duck) {
        duck.quack();    duck.walk();
    }
}

Textbook: Head First Design Patterns
The Facade Pattern

- Provides a unified interface to a set of interfaces in a subsystem.
- The facade defines a higher-level interface that makes the subsystem easier to use.
- Employs the principle of least knowledge.
That's a lot of classes, a lot of interactions, and a big set of interfaces to learn and use.
Scenario: Watching a movie

- **Steps:**
  1. Put the screen down
  2. Turn the projector on
  3. Set the projector input to DVD
  4. Put the projector on wide-screen mode
  5. Turn the sound amplifier on
  6. Set the amplifier to DVD input
  7. Set the amplifier to surround sound
  8. Set the amplifier volume to medium (5)
  9. Turn the DVD Player on
 10. Start the DVD Player playing
 11. Turn on the popcorn popper
 12. Start the popper popping
 13. Dim the lights
Scenario: Watching a movie

Let’s do it programmatically:

```java
popper.on();
popper.pop();

lights.dim(10);

screen.down();

projector.on();
projector.setInput(dvd);
projector.wideScreenMode();

amp.on();
amp.setDvd(dvd);
amp.setSurroundSound();
amp.setVolume(5);

dvd.on();
dvd.play(movie);
```

- Turn on the popcorn popper and start popping...
- Dim the lights to 10%...
- Put the screen down...
- Turn on the projector and put it in wide screen mode for the movie...
- Turn on the amp, set it to DVD, put it in surround sound mode and set the volume to 5...
- Turn on the DVD player... FINALLY, play the movie!
The Facade Pattern

• When the movie is over, how do you turn everything off?

• Wouldn’t you have to do all of this over again, in reverse?

• If you decide to upgrade your system, you’re probably going to have to learn a different procedure.
The Façade Pattern

The HomeTheaterFacade manages all those subsystem components for the client. It keeps the client simple and flexible.

We can upgrade the home theater components without affecting the client.

We try to keep subsystems adhering to the Principle of Least Knowledge as well. If this gets too complex and too many friends are intermingling, we can introduce additional facades to form layers of subsystems.

This client only has one friend: the HomeTheaterFacade. In OO programming, having only one friend is a GOOD thing!
public class HomeTheaterFacade {
    Amplifier amp;
    Tuner tuner;
    DvdPlayer dvd;
    CdPlayer cd;
    Projector projector;
    TheaterLights lights;
    Screen screen;
    ...
    public HomeTheaterFacade(Amplifier amp, Tuner tuner, DvdPlayer dvd, CdPlayer cd, Projector projector, Screen screen, TheaterLights lights, ...) { ... }
    public void watchMovie(String movie) {
        lights.dim(10);
        screen.down();
        projector.on();
        projector.wideScreenMode();
        amp.on();
        amp.setDvd(dvd);
        amp.setSurroundSound();
        amp.setVolume(5);
        dvd.on();
        dvd.play(movie);
    }
    public void endMovie() {
        lights.on();
        screen.up();
        projector.off();
        amp.off();
        dvd.stop();
        dvd.eject(); ...
    }
}
public class Main {
    public static void main(String[] args) {
        HomeTheaterFacade facade = new HomeTheaterFacade(
            new Amplifier(),
            new Tuner(),
            new DvdPlayer(),
            new CdPlayer(),
            new Projector(),
            new Screen(),
            new TheaterLights(),...);

        facade.watchMovie("The Croods: A New Age");
        facade.endMovie();
    }
}
class CPU {
    public void freeze() { ... }
    public void jump(long position) { ... }
    public void execute() { ... }
}

class Memory {
    public void load(long position, byte[] data) { ... }
}

class HardDrive {
    public byte[] read(long lba, int size) { ... }
}

/* Facade */
class ComputerFacade {
    private CPU processor;
    private Memory ram;
    private HardDrive hd;

    public ComputerFacade() {
        this.processor = new CPU();
        this.ram = new Memory();
        this.hd = new HardDrive();
    }

    public static void main(String[] args) {
        ComputerFacade computer = new ComputerFacade();
        computer.start();
    }
    public void start() {
        processor.freeze();
        ram.load(BOOT_ADDRESS, hd.read(BOOT_SECTOR, SECTOR_SIZE));
        processor.jump(BOOT_ADDRESS);
        processor.execute();
    }
}

A computer is a Façade to many components
Quiz: Which is which?

- Converts one interface to another  B
- Makes an interface simpler  C
- Doesn’t alter the interface, but adds responsibility  A

A) Decorator
B) Adapter
C) Facade
### Common Design Patterns

<table>

<td></td>
<td>• State</td>
</tr>
</tbody>
</table>

**Textbook:** Head First Design Patterns
Flyweight scenario

- You develop a landscape design application:

- After using your software for a week, your client is complaining that when they create large groves of trees, the app starts getting sluggish.
Flyweight scenario

- Flyweight: only one instance of Tree, and a client object that maintains the state of ALL the trees

```java
TreeManager

<table>
<thead>
<tr>
<th>treeArray</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayTrees()</td>
</tr>
<tr>
<td>// for all trees</td>
</tr>
<tr>
<td>// get array row</td>
</tr>
<tr>
<td>display(x, y, age);</td>
</tr>
<tr>
<td>}</td>
</tr>
</tbody>
</table>

Tree

<table>
<thead>
<tr>
<th>display(x, y, age)</th>
</tr>
</thead>
<tbody>
<tr>
<td>// use X-Y coords</td>
</tr>
<tr>
<td>// &amp; complex age</td>
</tr>
<tr>
<td>// related calcs</td>
</tr>
<tr>
<td>}</td>
</tr>
</tbody>
</table>

All the state, for ALL of your virtual Tree objects, is stored in this 2D-array.

One, single, state-free Tree object.
The Flyweight Pattern

- Allows one object to be used to represent many identical instances
  - The Flyweight is used when a class has many instances, and they can all be controlled identically.

- Flyweight Benefits:
  - Reduces the number of object instances at runtime, saving memory.
  - Centralizes state for many "virtual" objects into a single location.

- Flyweight Uses and Drawbacks:
  - Once you’ve implemented it, single, logical instances of the class will not be able to behave independently from the other instances.
The Flyweight Pattern

- Flyweights depend on an associated table
  - maps multiple instances to the single object that represents all of them
- the object must be immutable
- Used in processing many large documents like the Web
  - search engines will use an array of immutable Strings
    - all repeated Words would share the same objects referenced all over the place
      - use `static HashTable` to store mappings
import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

// Instances of CoffeeFlavour will be the Flyweights
class CoffeeFlavour {
    private final String name;
    CoffeeFlavour(String newFlavor) {
        this.name = newFlavor;
    }
    @Override
    public String toString() {
        return name;
    }
}

// Menu acts as a factory and cache for CoffeeFlavour flyweight objects
class Menu {
    private Map<String, CoffeeFlavour> flavours =
            new HashMap<String, CoffeeFlavour>();
    CoffeeFlavour lookup(String flavorName) {  // also uses Singleton
        if (!flavours.containsKey(flavorName))
            flavours.put(flavorName, new CoffeeFlavour(flavorName));
        return flavours.get(flavorName);
    }
    int totalCoffeeFlavoursMade() {
        return flavours.size();
    }

    Example:
    You have a CoffeeShop
class Order {
    private final int tableNumber;
    private final CoffeeFlavour flavour;
    Order(int tableNumber, CoffeeFlavour flavor) {
        this.tableNumber = tableNumber;
        this.flavour = flavor;
    }
    void serve() {
        System.out.println("Serving " + flavour + " to table " + tableNumber);
    }
}

class CoffeeShop {
    private final Menu menu = new Menu();
    private final List<Order> orders = new ArrayList<Order>();
    void takeOrder(String flavourName, int table) {
        CoffeeFlavour flavour = menu.lookup(flavourName);
        Order order = new Order(table, flavour);
        orders.add(order);
    }
    void service() {
        for (Order order : orders)
            order.serve();
    }
    String report() {
        return "total CoffeeFlavour objects made: " + menu.totalCoffeeFlavoursMade();
    }
}
public static void main(String[] args) {
    CoffeeShop shop = new CoffeeShop();
    shop.takeOrder("Cappuccino", 2);
    shop.takeOrder("Frappe", 1);
    shop.takeOrder("Espresso", 1);
    shop.takeOrder("Frappe", 8);
    shop.takeOrder("Cappuccino", 9);
    shop.takeOrder("Frappe", 3);
    shop.takeOrder("Espresso", 3);
    shop.takeOrder("Cappuccino", 3);
    shop.takeOrder("Cappuccino", 3);
    shop.takeOrder("Espresso", 9);
    shop.takeOrder("Frappe", 5);
    shop.takeOrder("Cappuccino", 1);
    shop.takeOrder("Espresso", 1);
    shop.service();
    System.out.println(shop.report());
}

Output:
Serving Cappuccino to table 2
Serving Frappe to table 1
Serving Espresso to table 1
Serving Frappe to table 8
Serving Cappuccino to table 9
Serving Frappe to table 3
Serving Espresso to table 3
...

Textbook: Head First Design Patterns
The Bridge Pattern

- Used to vary not only your implementations, but also your abstractions!
- Scenario:
  - you’re writing the code for a new ergonomic and user-friendly remote control for TVs
  - there will be lots of implementations – one for each model of TV – use an abstraction (interface)
  - you know there will be many changes over time to the specification – needs to accommodate changes
- Solution? **Abstract the abstraction.**
Scenario

- A bridge-less design
- Won’t easily accommodate change

This is an abstraction. It could be an interface or an abstract class.

Every remote has the same abstraction.

Lots of implementations, one for each TV.

Using this design we can vary only the TV implementation, not the user interface.
The Bridge Pattern

Abstraction class hierarchy.

The relationship between the two is referred to as the "bridge."

Implementation class hierarchy.

RemoteControl
- implementor
- on()
- off()
- setChannel()
  // more methods

Has-A

TV
- on()
- off()
- tuneChannel()
  // more methods

ConcreateRemote
- currentStation
- on()
- off()
- setStation()
- nextChannel()
- previousChannel()
  // more methods

RCA
- on()
- off()
- tuneChannel()
  // more methods

Sony
- on()
- off()
- tuneChannel()
  // more methods

All methods in the abstraction are implemented in terms of the implementation.

Concrete subclasses are implemented in terms of the abstraction, not the implementation.
The Bridge Pattern

• Benefits:
  • Decouples an implementation so that it is not bound permanently to an interface.
  • Abstraction and implementation can be extended independently.
  • Changes to the concrete abstraction classes don’t affect the client.
  • Useful in graphics and windowing systems that need to run over multiple platforms.
  • Useful any time you need to vary an interface and an implementation in different ways.

• Bridge Drawback:
  • Increases complexity
/** "Abstraction" */
abstract class Shape {
    protected DrawingAPI drawingAPI;
    protected Shape(DrawingAPI drawingAPI) {
        this.drawingAPI = drawingAPI;
    }
