

Behavioral Design Patterns

Paul Fodor

CSE316: Fundamentals of Software
Development

Stony Brook University

<http://www.cs.stonybrook.edu/~cse316>

Behavioral Design Patterns

- Design patterns that identify common communication patterns between objects and realize these patterns.
 - they increase the flexibility in carrying out communication

Behavioral Design Patterns

- **Strategy pattern**: algorithms can be selected on the fly
- **Template method pattern**: describes the program skeleton of a program
- **Observer pattern**: objects register to observe an event that may be raised by another object (i.e., Event Listener)
- **Command pattern**: command objects encapsulate an action and its parameters
- **Iterator pattern**: iterators are used to access the elements of an aggregate object sequentially without exposing its underlying representation
- **State pattern**: a clean way for an object to partially change its type at runtime

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

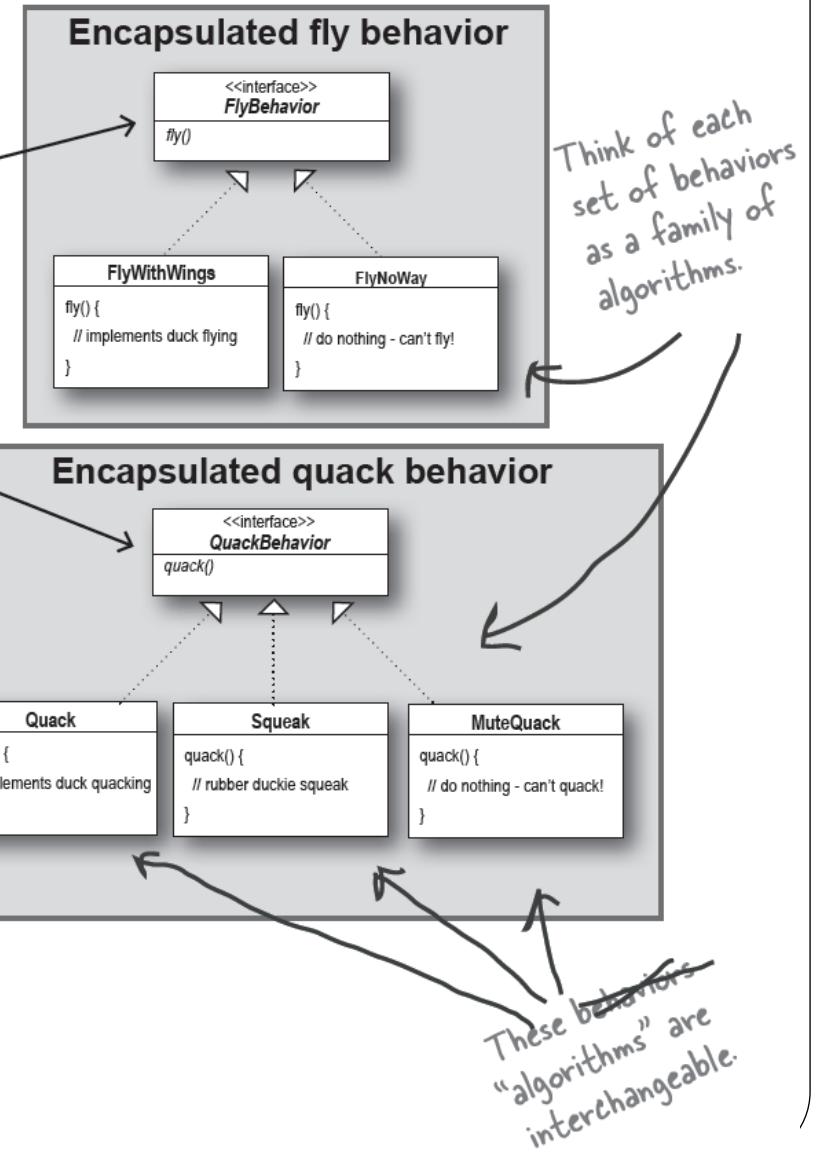

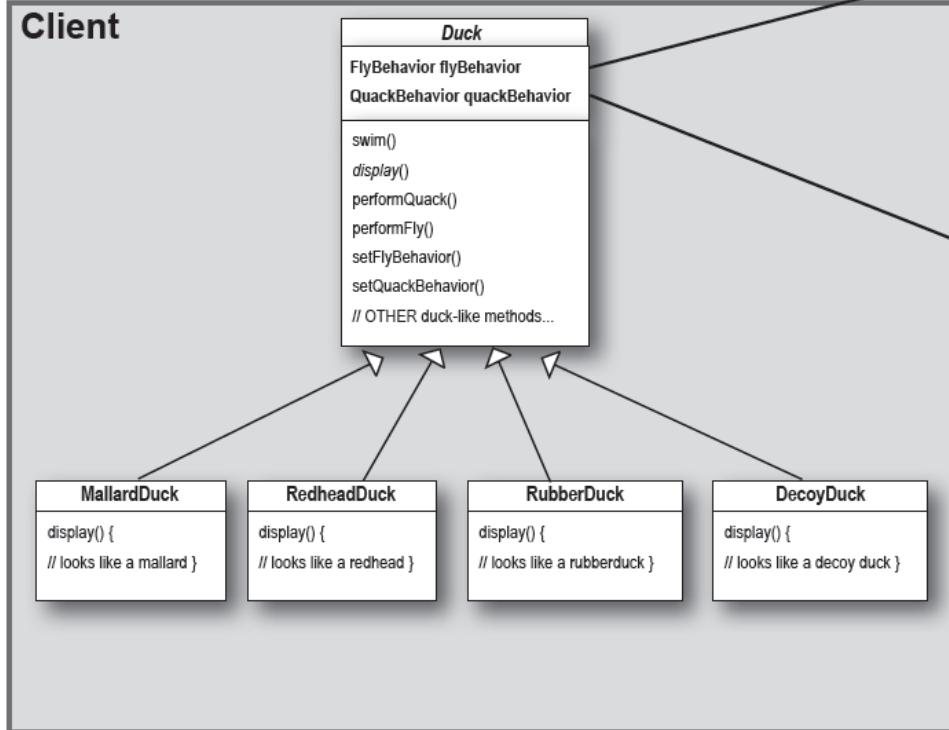

- **Strategy**
- Template
- Observer
- Command
- Iterator
- State

The Strategy Pattern

- Defines a family of algorithms, encapsulates each one, and makes them interchangeable
 - lets the algorithm vary independently from the clients that use them
- An algorithm in a box
 - place essential steps for an algorithm in a strategy interface
 - different methods represent different parts of the algorithm
 - **classes implementing this interface customize methods**
- Classes can be composed (HAS-A) of the interface type
 - the interface type is the apparent type
 - the actual type can be determined at run-time

The Strategy Pattern Example

Client makes use of an encapsulated family of algorithms for both flying and quacking.

StrategyExample.java

```
abstract class Duck {
    FlyBehaviour flyBehaviour;
    QuackBehaviour quackBehaviour;
    public void fly() {
        this.flyBehaviour.fly();
    }
    public void quack() {
        this.quackBehaviour.quack();
    }
}
interface FlyBehaviour {
    void fly();
}
class FlyWithWings implements FlyBehaviour {
    public void fly() {
        System.out.println("Flying with wings ...");
    }
}
class FlyNoWay implements FlyBehaviour {
    public void fly() {
        System.out.println("Cannot Fly.");
    }
}
interface QuackBehaviour {
    void quack();
}
class Quack implements QuackBehaviour {
    public void quack() {
        System.out.println("Quack quack ...");
    }
}
```

(c) Paul Fodor & O'Reilly Media

```
class RubberQuack implements QuackBehaviour {
    public void quack() {
        System.out.println("Quick quack . . .");
    }
}

class MallardDuck extends Duck{
    public MallardDuck() {
        this.flyBehaviour = new FlyWithWings();
        this.quackBehaviour = new Quack();
    }
}

class RubberDuck extends Duck{
    public RubberDuck() {
        this.flyBehaviour = new FlyNoWay();
        this.quackBehaviour = new RubberQuack();
    }
}

public class StrategyExample {
    public static void main(String[] args) {
        Duck duck = new MallardDuck();
        duck.fly();
        duck.quack();

        duck = new RubberDuck();
        duck.fly();
        duck.quack();
    }
}
```

The Strategy Pattern

- We are using composition instead of inheriting their behavior: the ducks get their behavior by being composed with the right behavior object.
- The HAS-A relationship can be better than IS-A
 - In the example, each duck has a FlyBehavior and a QuackBehavior to which it delegates flying and quacking.
 - It also allows to *change the behavior at runtime* as long as the object implements the correct behavior interface.

```
/** Calculator.java using the strategy pattern
 * The classes that implement a concrete strategy should implement Strategy
 * interface.
 * The Context class uses this to call the concrete strategy. */
interface Strategy {
    int execute(int a, int b);
}

/** Implements the algorithm using the strategy interface */
class Add implements Strategy {
    public int execute(int a, int b) {
        System.out.println("Called Add's execute()");
        return a + b; // Do an addition with a and b
    }
}

class Subtract implements Strategy {
    public int execute(int a, int b) {
        System.out.println("Called Subtract's execute()");
        return a - b; // Do a subtraction with a and b
    }
}

class Multiply implements Strategy {
    public int execute(int a, int b) {
        System.out.println("Called Multiply's execute()");
        return a * b; // Do a multiplication with a and b
    }
}
```

```
// Configured with a ConcreteStrategy object and maintains
// a reference to a Strategy object
class Context {
    private Strategy strategy;
    public Context(Strategy strategy) {
        this.strategy = strategy;
    }
    public int executeStrategy(int a, int b) {
        return this.strategy.execute(a, b);
    }
}

public class Calculator {
    public static void main(String[] args) {
        Context context;
        // Three contexts following different strategies
        context = new Context(new Add());
        int resultA = context.executeStrategy(3,4);
        System.out.println("Result A : " + resultA );

        context = new Context(new Subtract());
        int resultB = context.executeStrategy(3,4);
        System.out.println("Result B : " + resultB );

        context = new Context(new Multiply());
        int resultC = context.executeStrategy(3,4);
        System.out.println("Result C : " + resultC );
    }
}
```

Strategy Patterns in the Java API

- **LayoutManagers** interface in SWING
 - describes how to arrange components:
 - components added to or removed from the container.
 - automatic resizing and position the components it manages

```
public interface LayoutManager {  
    void addLayoutComponent(String name, Component comp);  
    void removeLayoutComponent(Component comp);  
    Dimension preferredLayoutSize(Container parent);  
    Dimension minimumLayoutSize(Container parent);  
    void layoutContainer(Container parent);  
}
```

Containers use LayoutManagers

- Composition / at runtime:

```
public class Container extends Component {  
    private List<Component> component;  
    private LayoutManager layoutMgr;  
  
    ...  
    public void setLayout(LayoutManager mgr) {  
        layoutMgr = mgr;  
    }  
}
```

Dynamic interchange

- Interchangeable layout algorithms:

```
public void initGUI() {  
    panel = new JPanel();  
    panel.setLayout(new FlowLayout());  
    // panel.setLayout(new VBoxLayout());  
    panel.add(new JButton("Ok"));  
    panel.add(new JButton("Cancel"));  
}
```

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

- Strategy
- **Template**
- Observer
- Command
- Iterator
- State

Template Method Pattern

- A template for a general algorithm
- Defines the skeleton of an algorithm in a method, deferring some steps to subclasses.
- Lets subclasses redefine certain steps of an algorithm without changing the algorithm's structure.

Template Method Pattern

- Example: Starbuzz beverages are similar
 - Coffee:
 - (1) Boil some water
 - (2) Brew coffee in boiling water
 - (3) Pour coffee in cup
 - (4) Add sugar and milk
 - Tea: // eliminate code duplication
 - (1) Boil some water
 - (2) Steep tea in boiling water
 - (3) Pour tea in cup
 - (4) Add lemon

Template Method Pattern

```
CaffeineBeverage is abstract, just  
like in the class design.  
  
public abstract class CaffeineBeverage {  
  
    final void prepareRecipe() {  
        boilWater();  
        brew();  
        pourInCup();  
        addCondiments();  
    }  
  
    abstract void brew();  
  
    abstract void addCondiments();  
  
    void boilWater() {  
        System.out.println("Boiling water");  
    }  
  
    void pourInCup() {  
        System.out.println("Pouring into cup");  
    }  
}
```

Now, the same `prepareRecipe()` method will be used to make both Tea and Coffee. `prepareRecipe()` is declared final because we don't want our subclasses to be able to override this method and change the recipe! We've generalized steps 2 and 4 to `brew()` the beverage and `addCondiments()`.

Because Coffee and Tea handle these methods in different ways, they're going to have to be declared as abstract. Let the subclasses worry about that stuff!

Remember, we moved these into the `CaffeineBeverage` class (back in our class diagram).

Template Method Pattern

```
public class Tea extends CaffeineBeverage {  
    public void brew() {  
        System.out.println("Steeping the tea");  
    }  
    public void addCondiments() {  
        System.out.println("Adding Lemon");  
    }  
}
```

As in our design, Tea and Coffee now extend CaffeineBeverage.

```
public class Coffee extends CaffeineBeverage {  
    public void brew() {  
        System.out.println("Dripping Coffee through filter");  
    }  
    public void addCondiments() {  
        System.out.println("Adding Sugar and Milk");  
    }  
}
```

Tea needs to define brew() and addCondiments() – the two abstract methods from Beverage.

Same for Coffee, except Coffee deals with coffee, and sugar and milk instead of tea bags and lemon.

We've recognized that the two recipes are essentially the same, although some of the steps require different implementations. So we've generalized the recipe and placed it in the base class.

Tea

- ① Boil some water
- ② Steep the teabag in the water
- ③ Pour tea in a cup
- ④ Add lemon

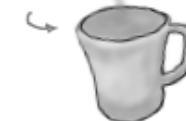

Coffee

- ① Boil some water
- ② Brew the coffee grinds
- ③ Pour coffee in a cup
- ④ Add sugar and milk

Caffeine Beverage

- ① Boil some water
- ② Brew
- ③ Pour beverage in a cup
- ④ Add condiments

Tea subclass
relies on subclass for some steps

- ② Steep the teabag in the water
- ④ Add lemon

Coffee subclass
relies on subclass for some steps

- ③ Brew the coffee grinds
- ④ Add sugar and milk

prepareRecipe() is our template method.
Why?

Because:

(1) It is a method, after all.

(2) It serves as a template for an algorithm, in this case, an algorithm for making caffeinated beverages.

In the template, each step of the algorithm is represented by a method.

Some methods are handled by this class...

...and some are handled by the subclass.

The methods that need to be supplied by a subclass are declared abstract.

```
public abstract class CaffeineBeverage {  
  
    void final prepareRecipe() {  
  
        boilWater();  
  
        brew();  
  
        pourInCup();  
  
        addCondiments();  
    }  
  
}
```

```
abstract void brew();
```

```
abstract void addCondiments();
```

```
void boilWater() {  
    // implementation  
}
```

```
void pourInCup() {  
    // implementation  
}
```

1

Okay, first we need a Tea object...

```
Tea myTea = new Tea();
```

```
boilWater();  
brew();  
pourInCup();  
addCondiments();
```

2

Then we call the template method:

```
myTea.prepareRecipe();
```

which follows the algorithm for making caffeine beverages...

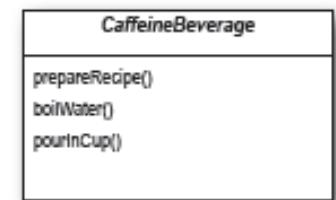

The `prepareRecipe()` method controls the algorithm, no one can change this, and it counts on subclasses to provide some or all of the implementation.

3

First we boil water:

```
boilWater();
```

which happens in CaffeineBeverage.

4

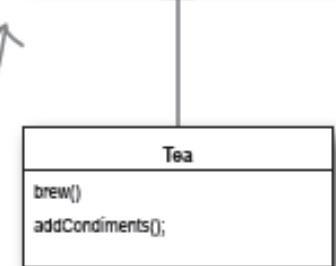

Next we need to brew the tea, which only the subclass knows how to do:

```
brew();
```

5

Now we pour the tea in the cup; this is the same for all beverages so it happens in CaffeineBeverage:

```
pourInCup();
```

6

Finally, we add the condiments, which are specific to each beverage, so the subclass implements this:

```
addCondiments();
```

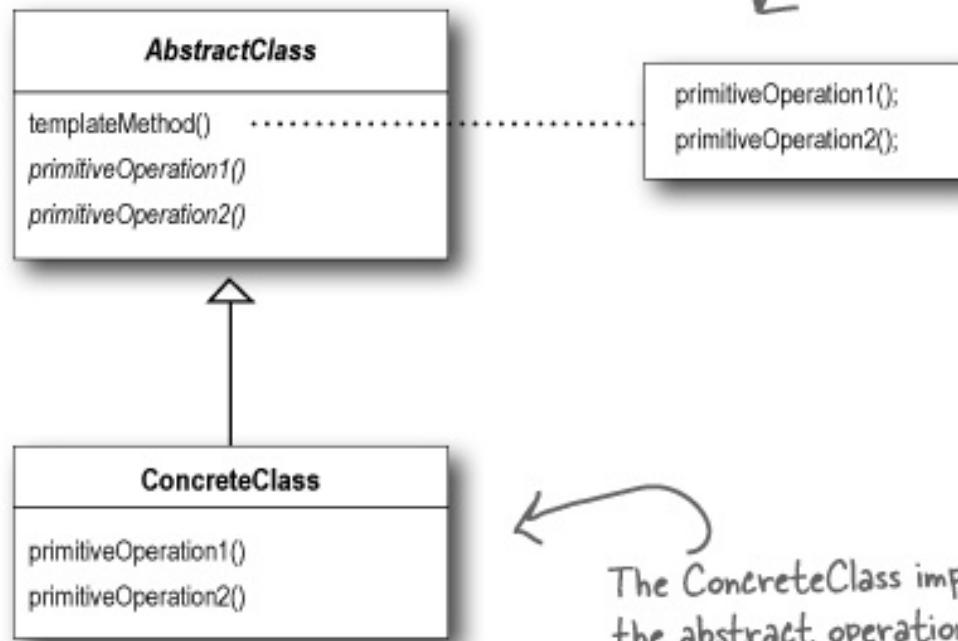

Template Method Pattern

The template method makes use of the primitiveOperations to implement an algorithm. It is decoupled from the actual implementation of these operations.

The AbstractClass contains the template method.

...and abstract versions of the operations used in the template method.

There may be many ConcreteClasses, each implementing the full set of operations required by the template method.

primitiveOperation1();
primitiveOperation2();

The ConcreteClass implements the abstract operations, which are called when the templateMethod() needs them.

Template Method Pattern

We've changed the templateMethod() to include a new method call.

```
abstract class AbstractClass {  
  
    final void templateMethod() {  
        primitiveOperation1();  
        primitiveOperation2();  
        concreteOperation();  
        hook();  
    }  
  
    abstract void primitiveOperation1();  
  
    abstract void primitiveOperation2();  
  
    final void concreteOperation() {  
        // implementation here  
    }  
  
    void hook() {}  
}
```

A concrete method, but it does nothing!

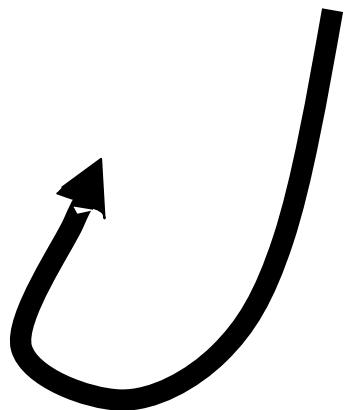

We still have our primitive methods; these are abstract and implemented by concrete subclasses.

A concrete operation is defined in the abstract class. This one is declared final so that subclasses can't override it. It may be used in the template method directly, or used by subclasses.

We can also have concrete methods that do nothing by default; we call these "hooks." Subclasses are free to override these but don't have to. We're going to see how these are useful on the next page.

What's a hook?

- A method only declared in the abstract class
 - only given an empty or default implementation
- Gives subclasses the ability to "hook into" the algorithm at various points, if they wish
 - a subclass is also free to ignore the hook.

```

public abstract class CaffeineBeverageWithHook {

    void prepareRecipe() {
        boilWater();
        brew();
        pourInCup();
        if (customerWantsCondiments()) {
            addCondiments();
        }
    }

    abstract void brew();

    abstract void addCondiments();

    void boilWater() {
        System.out.println("Boiling water");
    }

    void pourInCup() {
        System.out.println("Pouring into cup");
    }

    boolean customerWantsCondiments() {
        return true;
    }
}

```

We've added a little conditional statement that bases its success on a concrete method, `customerWantsCondiments()`. If the customer WANTS condiments, only then do we call `addCondiments()`.

Here we've defined a method with a (mostly) empty default implementation. This method just returns true and does nothing else.

This is a hook because the subclass can override this method, but doesn't have to.

```
abstract class CaffeineBeverage {                                // Starbuzz.java
    public final void prepareRecipe() {
        boilWater();
        brew();
        pourInCup();
        addCondiments();
        hook();
    }
    void boilWater() {
        System.out.println("Boiling water ...");
        hookWaterHasBoiled();
    }
    void pourInCup() {
        System.out.println("Pour fluid in cup.");
    }
    abstract void brew();
    abstract void addCondiments();
    void hook(){}
    void hookWaterHasBoiled(){}
}
class Coffee extends CaffeineBeverage {
    @Override
    void brew() {
        System.out.println("Brew/filter the coffee ...");
    }
    @Override
    void addCondiments() {
        System.out.println("Add milk and sugar to the coffeee.");
    }
}
```

```
    @Override
    void hook() {
        System.out.println("Did you like the coffee?");
    }
}

class Tea extends CaffeineBeverage {
    @Override
    void brew() {
        System.out.println("Put teabag in the water.");
    }
    @Override
    void addCondiments() {
        System.out.println("Add sugar and honey to the tea");
    }
    @Override
    void hookWaterHasBoiled() {
        System.out.println("The tea water is boiling!!!!");
    }
}

public class Starbuzz {
    public static void main(String[] args) {
        CaffeineBeverage beverage = new Coffee();
        beverage.prepareRecipe();

        beverage = new Tea();
        beverage.prepareRecipe();
    }
}
```

Strategy vs. Template Method

- What's the difference?
- Strategy
 - encapsulate interchangeable behaviors and use delegation to decide which behavior to use
- Template Method
 - subclasses decide how to implement steps in an algorithm

```
/** An abstract class that is common to several games in which players play
 * against the others, but only one is playing at a given time.
 */
abstract class Game {
    protected int playersCount;
    abstract void initializeGame();
    abstract void makePlay(int player);
    abstract boolean endOfGame();
    abstract void printWinner();
    /* A template method: */
    public final void playOneGame(int playersCount) {
        this.playersCount = playersCount;
        initializeGame();
        int j = 0;
        while (!endOfGame()) {
            makePlay(j);
            j = (j + 1) % playersCount;
        }
        printWinner();
    }
}
//Now we can extend this class in order
//to implement actual games:
class Monopoly extends Game {
    /* Implementation of necessary concrete methods */
    void initializeGame() {
        // Initialize players
        // Initialize money
    }
}
```

Play template example

```
void makePlay(int player) {
    // Process one turn of player
}
boolean endOfGame() {
    // Return true if game is over
    // according to Monopoly rules
}
void printWinner() {
    // Display who won
}
/* Specific declarations for the Monopoly game. */
}

class Chess extends Game {
    /* Implementation of necessary concrete methods */
    void initializeGame() {
        // Initialize players
        // Put the pieces on the board
    }
    void makePlay(int player) {
        // Process a turn for the player
    }
    boolean endOfGame() {
        // Return true if in Checkmate or
        // Stalemate has been reached
    }
    void printWinner() {
        // Display the winning player
    }
    /* Specific declarations for the chess game. */
}
```

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

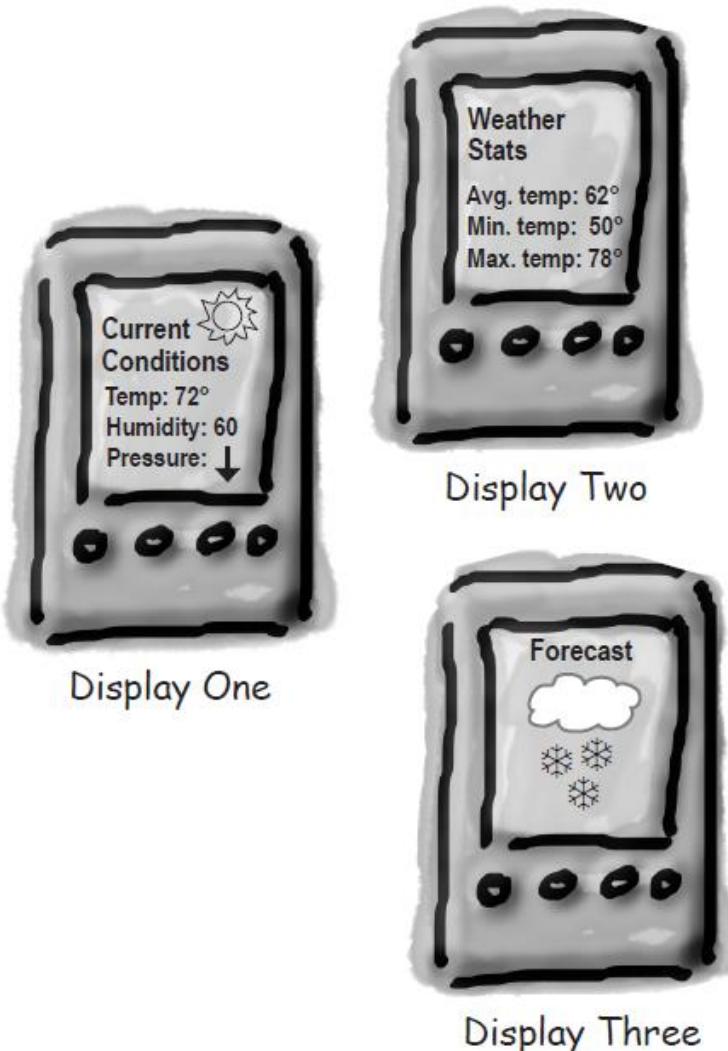

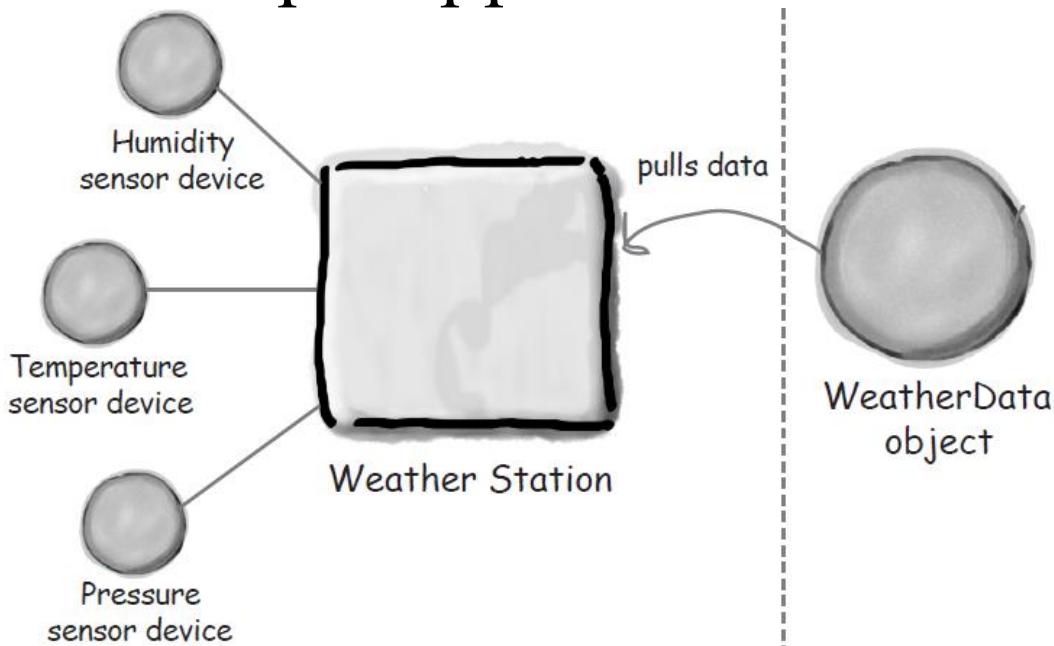

- Strategy
- Template
- **Observer**
- Command
- Iterator
- State

The Observer Pattern

- Defines a one-to-many dependency between objects so that **when one object changes state, all of its dependents are notified and updated automatically**
- Where have we seen this?
 - in our GUI
 - State Manager class maintains application's state
 - call methods to change app's state
 - app's state change forces update of GUI

The Observer Pattern

- Example: a WeatherData object is "*observed*" by multiple apps.

```
import java.util.ArrayList;           // ObserverWeather.java
import java.util.List;

class Observable {
    List<Observer> observers = new ArrayList<Observer>();
    void publish(Object data) {
        for (Observer obs : this.observers) {
            obs.update(this,data);
        }
    }
    public void subscribe(Observer obs) {
        this.observers.add(obs);
    }
    public void unsubscribe(Observer obs) {
        this.observers.remove(obs);
    }
}

interface Observer {
    void update(Observable observable, Object object);
}

class WeatherData extends Observable {
    int temperature;
    public void update(int newTemperature) {
        this.temperature = newTemperature;
        this.publish(new Integer(temperature));
    }
}
```

```
class WeatherStation implements Observer {
    public WeatherStation(WeatherData obs) {
        obs.subscribe(this);
    }
    @Override
    public void update(Observable observable, Object object) {
        if (observable instanceof WeatherData
            && object instanceof Integer) {
            Integer temp = (Integer) object;
            System.out.println("Station: temperature is " + temp);
        }
    }
}

public class ObserverWeather {
    public static void main(String[] args) {
        WeatherData data = new WeatherData();

        WeatherStation station1 = new WeatherStation(data);
        WeatherStation station2 = new WeatherStation(data);
        data.update(40);

        data.unsubscribe(station1);
        System.out.println("deleted one");

        data.update(35);
    }
}
```

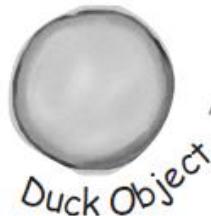

Publishers + Subscribers = Observer Pattern

Subject object manages some bit of data.

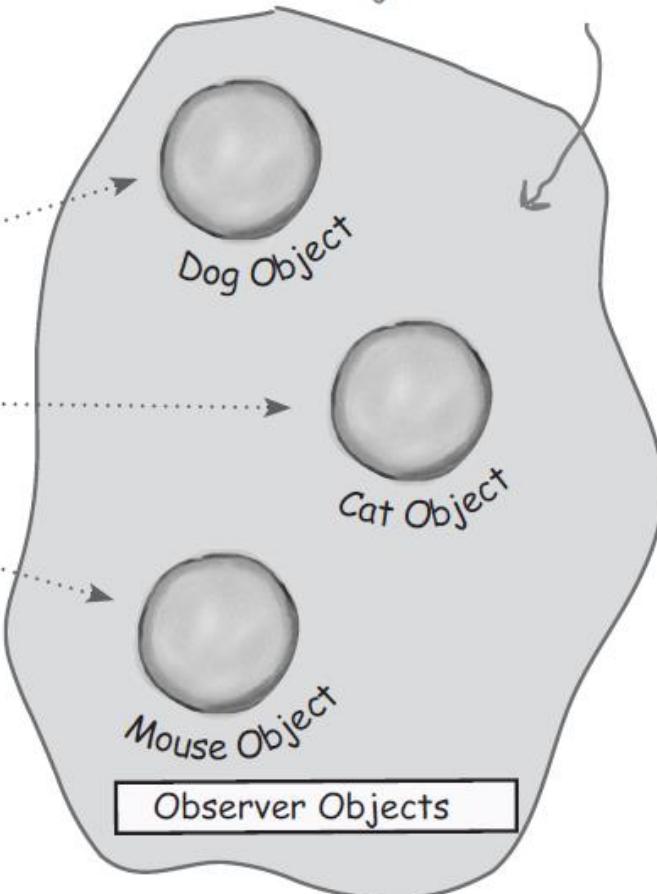

When data in the Subject changes, the observers are notified.

New data values are communicated to the observers in some form when they change.

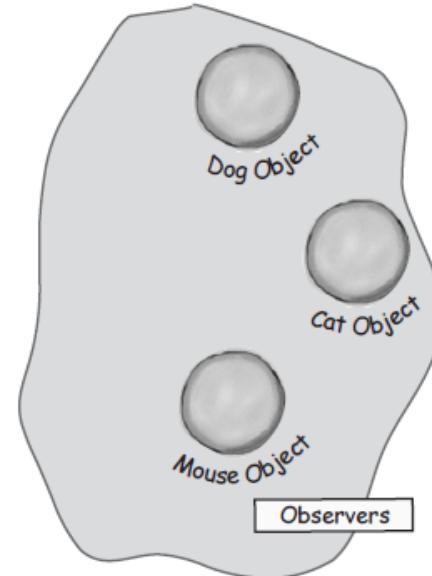

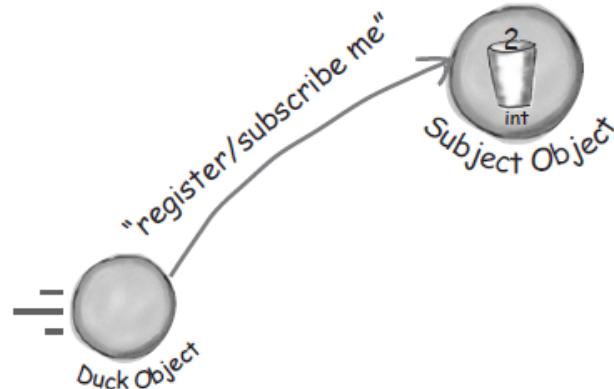

This object isn't an observer, so it doesn't get notified when the Subject's data changes.

The observers have subscribed to (registered with) the Subject to receive updates when the Subject's data changes.

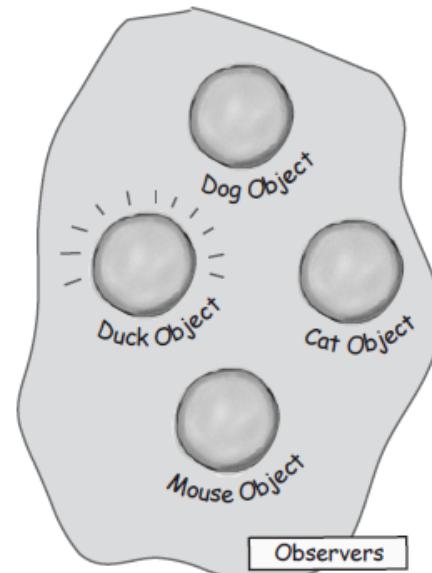

A Duck object comes along and tells the Subject that it wants to become an observer.

Duck really wants in on the action; those ints Subject is sending out whenever its state changes look pretty interesting...

The Duck object is now an official observer.

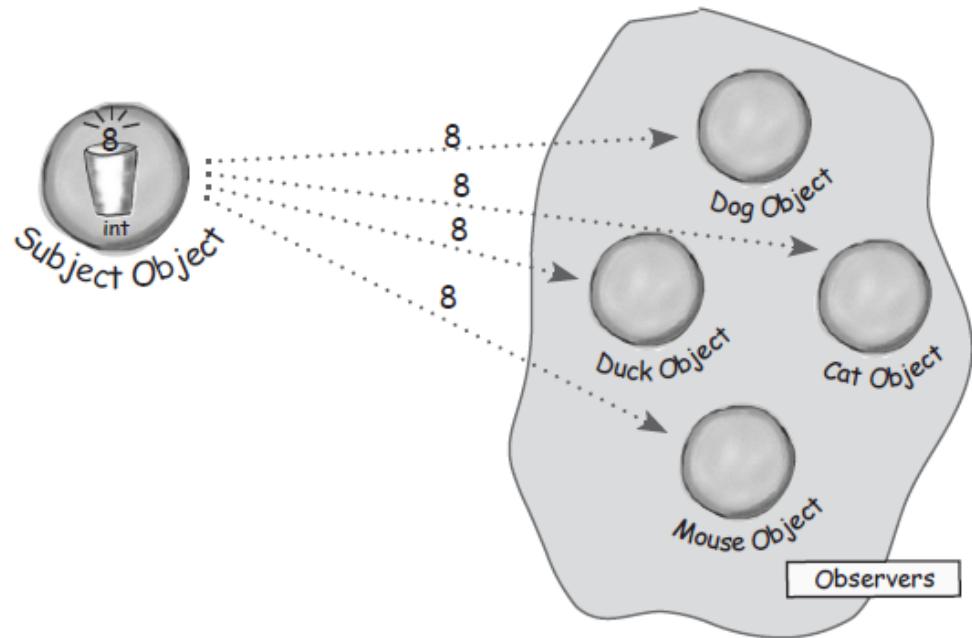

Duck is psyched... he's on the list and is waiting with great anticipation for the next notification so he can get an int.

The Observer Pattern

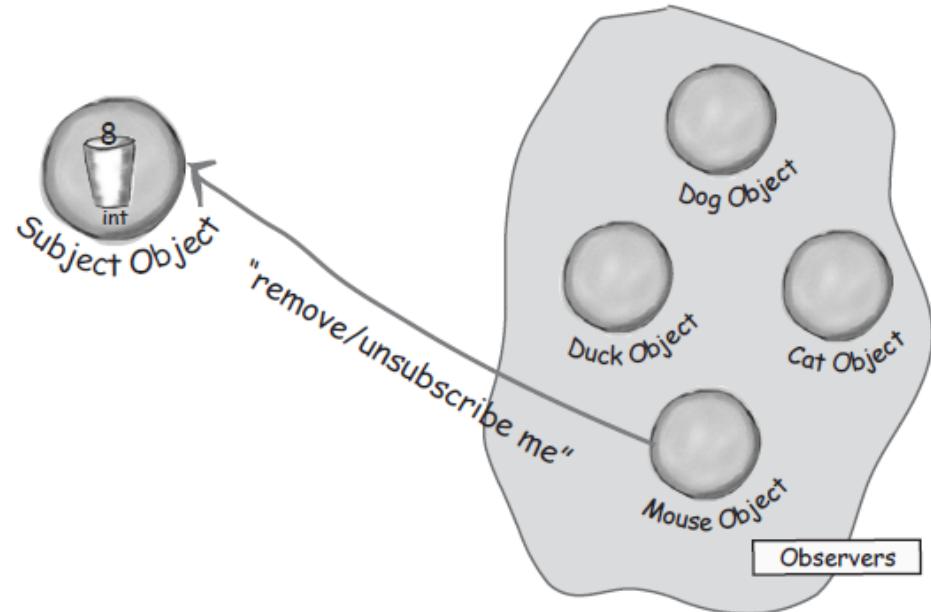

The Subject gets a new data value!

Now Duck and all the rest of the observers get a notification that the Subject has changed.

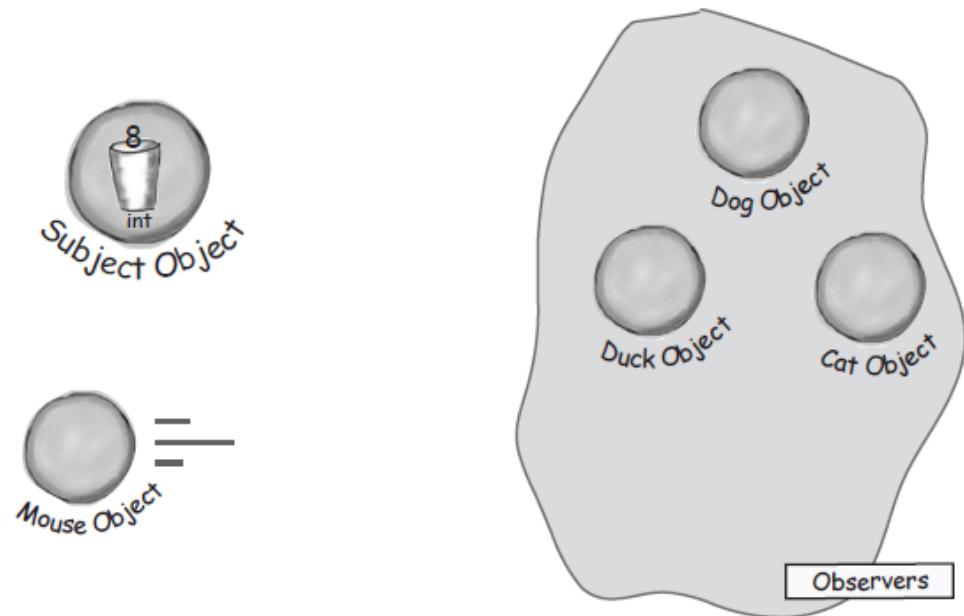

The Mouse object asks to be removed as an observer.

The Mouse object has been getting ints for ages and is tired of it, so it decides it's time to stop being an observer.

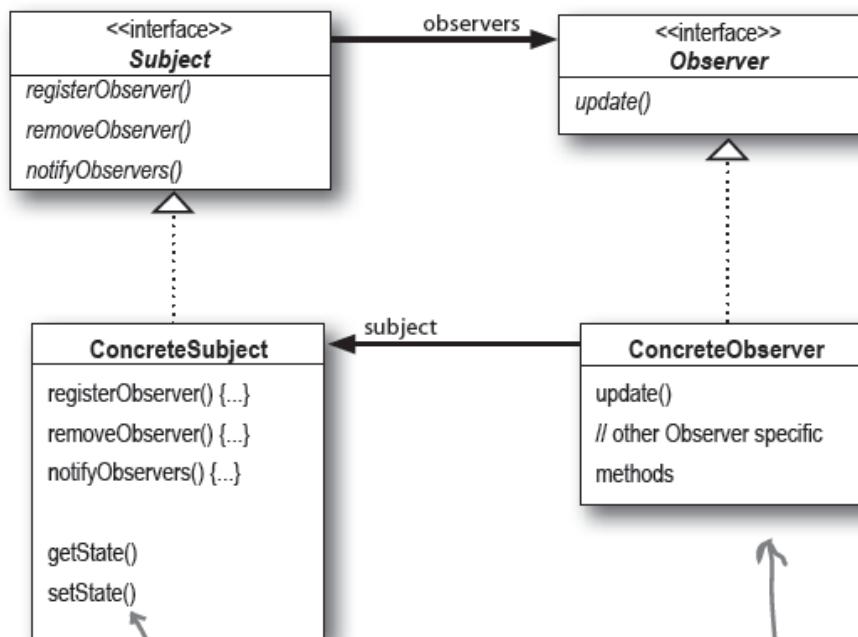

Mouse is outta here!

The Subject acknowledges the Mouse's request and removes it from the set of observers.

The Observer Pattern defined: the class diagram

Here's the Subject interface.
Objects use this interface to register
as observers and also to remove
themselves from being observers.

A concrete subject always
implements the Subject
interface. In addition to
the register and remove
methods, the concrete subject
implements a `notifyObservers()`
method that is used to update
all the current observers
whenever state changes.

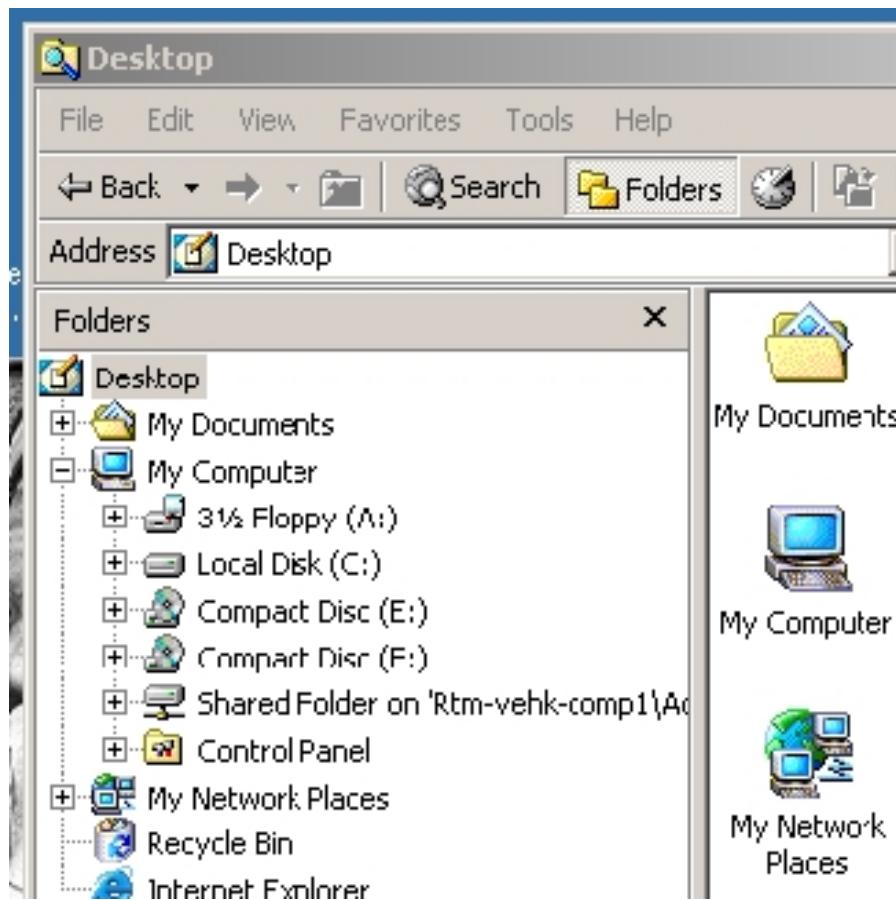

The concrete subject may also
have methods for setting and
getting its state (more about
this later).

Each subject
can have many
observers.

All potential observers need
to implement the Observer
interface. This interface
just has one method, `update()`,
that gets called when the
Subject's state changes.

JTrees

- Used to display a hierarchical structure
 - File structure, browsing history, etc...

Editing

- To edit the tree, you must go through the model:

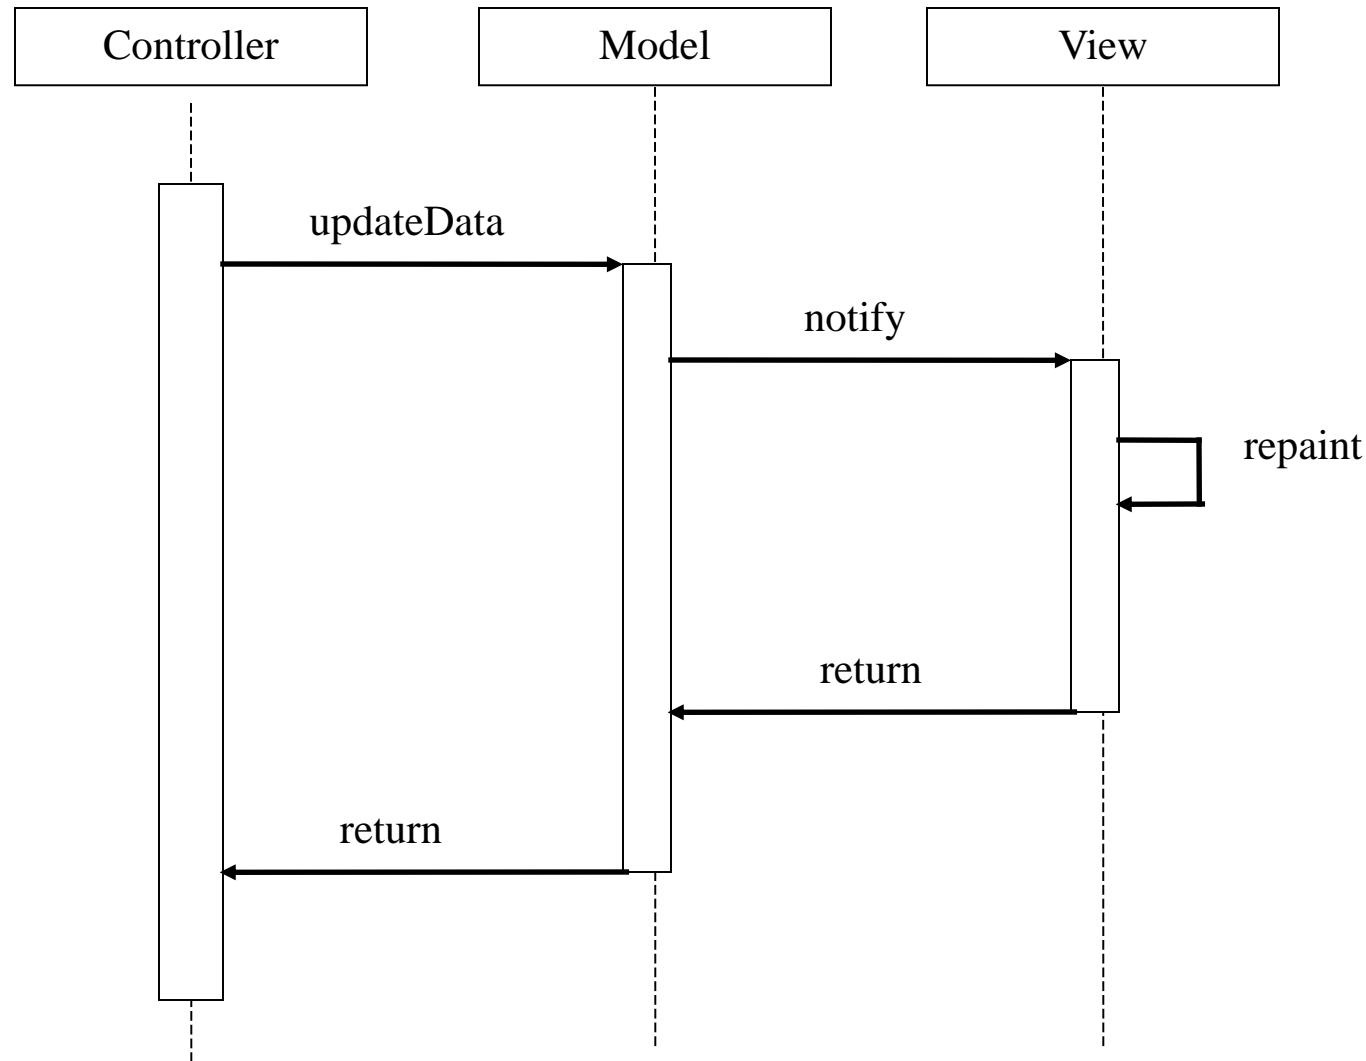

```
JTree tree = new JTree(...);  
TreeModel model = tree.getModel();  
  
// Insert Node  
model.insertNodeInto(...  
  
// Remove Node  
model.removeNodeFromParent(...  
  
// Change Node  
model.nodeChanged(...  
  
// UPDATING THE MODEL WILL NOW AUTOMATICALLY UPDATE  
// THE VIEW (JTree) THANKS TO MVC!
```

Complex Controls have their own States

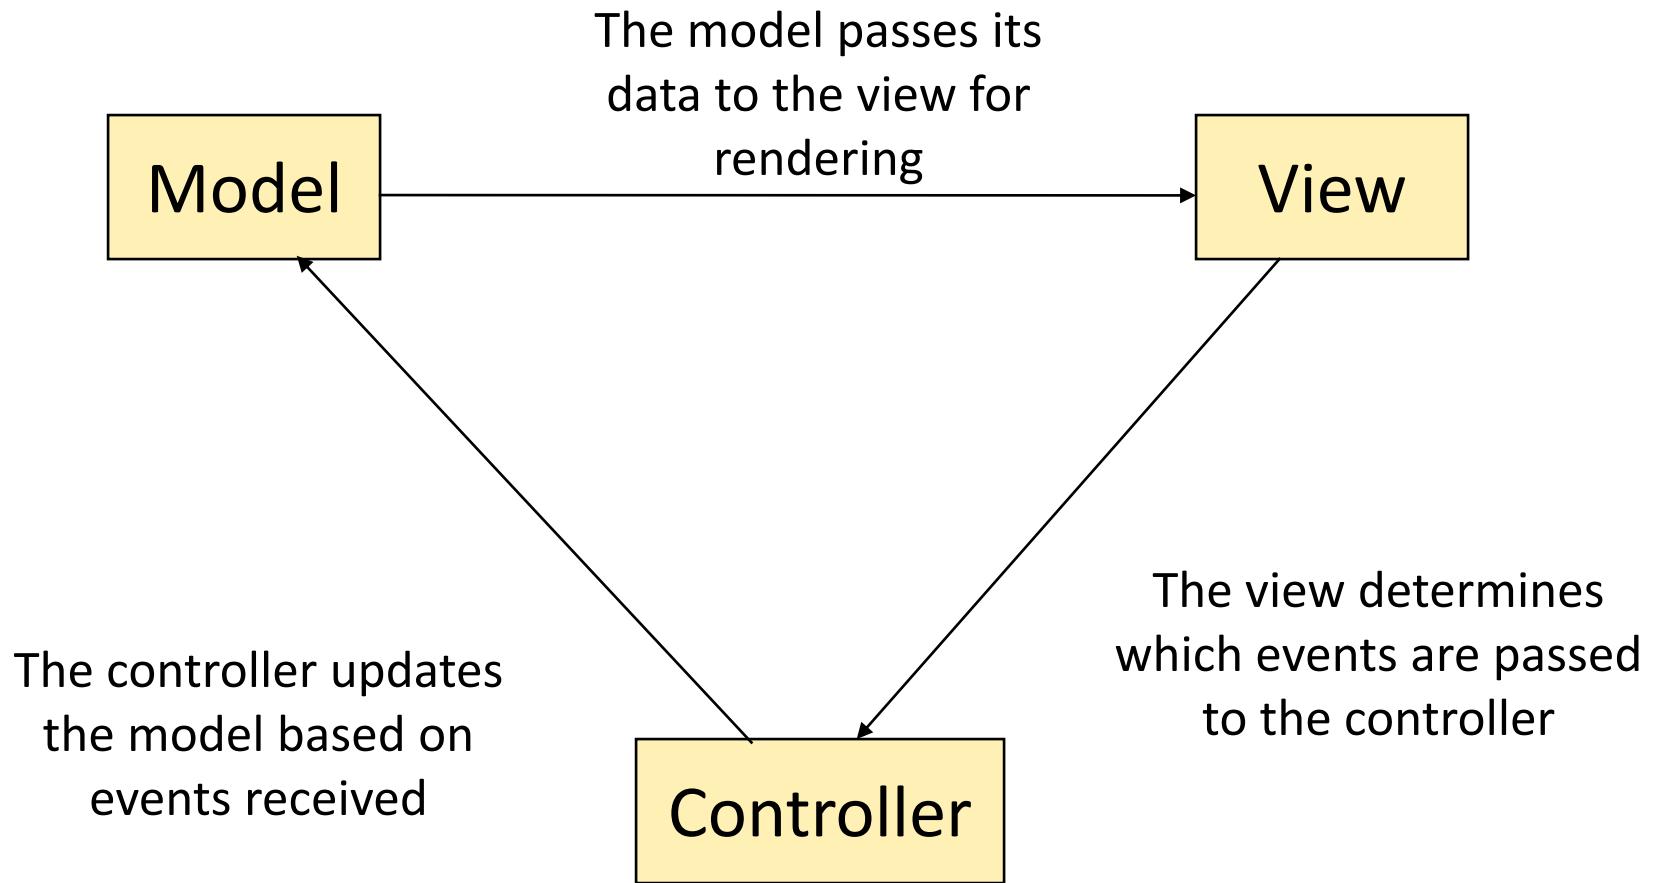

- Tables, trees, lists, combo boxes, etc.
 - data is managed separately from the view
 - when the state changes, the view is updated
- This is called **MVC**
 - Model
 - View
 - Controller
- MVC employs the Observer Pattern

MVC employs the Observer Pattern

- Model
 - data structure, no visual representation
 - notifies views when something interesting happens
- View / Observer
 - visual representation
 - views attach themselves to model in order to be notified
- Controller
 - event handler
 - listeners that are attached to view in order to be notified of user interaction (or otherwise)
- MVC Interaction
 - controller updates model
 - model tells view that data has changed
 - view redrawn

MVC Architecture

GUIs love MVC

| Model | View | Controller |
|------------------------|--------------------|--------------------------------|
| • ComboBoxModel | – JComboBox | – ItemListener |
| • ListModel | – JList | – ListSelectionListener |
| • TableModel | – JTable | – CellEditorListener |
| • TreeModel | – JTree | – TreeSelectionListener |
| ... | | |

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

- Strategy
- Template
- Observer
- **Command**
- Iterator
- State

Command Abstraction

- For many GUIs, a single function may be triggered by many means (e.g., keystroke, menu, button, etc...)
 - we want to link all similar events to the same listener
- The information concerning a command can be abstracted to a separate **command object**
- **The Command Pattern** Common Approach:
 - specify a String for each command
 - have listener respond to each command differently
 - ensures commands are handled in a uniform way
 - commands can be specified inside a text file

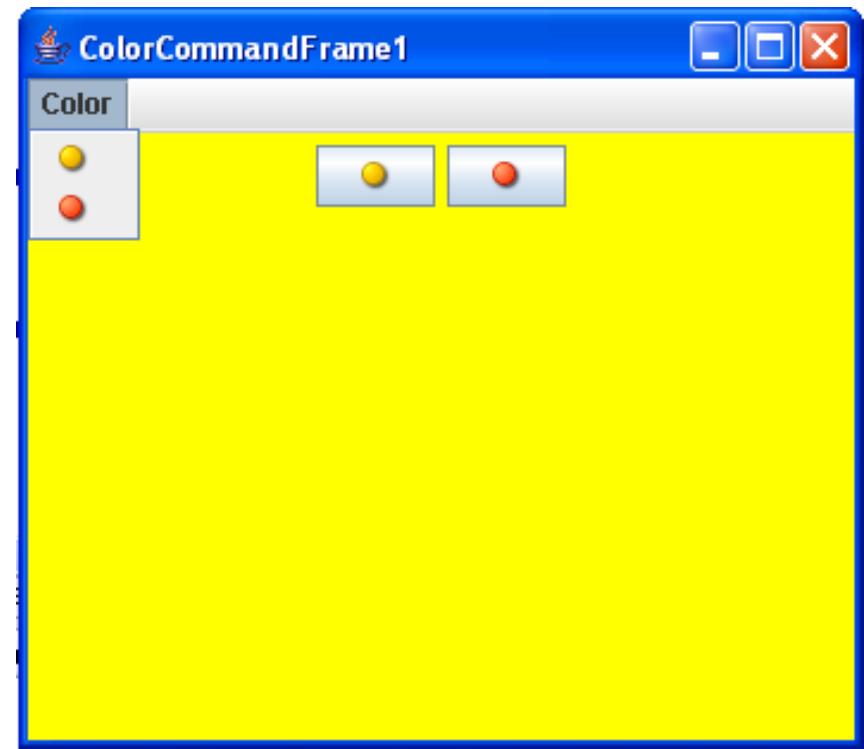

- Suppose I wanted to create a simple GUI:

- 1 colored panel
 - 2 buttons, yellow & red
 - 2 menu items, yellow & red
 - clicking on the buttons or menu items changes the color of the panel

- Since the buttons & the menu items both perform the same function, they should be tied to the same commands

- I could even add popup menu items or other means to change the colors

Example

```
import java.awt.*;
import java.awt.event.*;
import javax.swing.*;
public class ColorCommandFrame extends JFrame
    implements ActionListener {
    private Toolkit tk = Toolkit.getDefaultToolkit();
    private ImageIcon yellowIcon
        = new ImageIcon(tk.getImage("yellow_bullet.bmp"));
    private ImageIcon redIcon
        = new ImageIcon(tk.getImage("red_bullet.bmp"));

Output:
The light is true
The door is true

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

- Strategy
- Template
- Observer
- Command
- **Iterator**
- State

The Iterator Pattern

- The iterator pattern is a design pattern in which an iterator is used to traverse a container and access the container's elements: "*you have to perform some operation on a sequence of elements in a given data structure*"
 - it decouples algorithms from containers,
 - the iterator object will maintain the state of the iteration, keeping track of the current item and having a way of identifying what elements are next to be iterated.

The Iterator Pattern

- An **Iterator** produces proper elements for processing
- Using an Iterator must be simple
 - they're all used in the same way
- E.g. **update()** all elements of **List list**:

```
Iterator it;  
for (it=list.listIterator(); it.hasNext(); )  
    it.next().update();
```

- Makes iteration through elements of a set "higher level"
- Separates the *production* of elements for iteration from the *operation* at each step in the iteration.

The Iterator Pattern

- Common Classes using Iterators in Java API
 - Vector, ArrayList, etc ...
 - I/O streams work like Iterators
 - StringTokenizer
- Iterator is a design pattern that is encountered very often.
 - Problem: Defining an Iterator may be complex
 - Solution: The COLLECTION is represented in some data structure (list, array, hashtable, etc.)

java.util.Iterator

```
public interface Iterator {  
    // Returns true if there are more  
    // elements to iterate over; false  
    // otherwise  
    public boolean hasNext();  
  
    // If there are more elements to  
    // iterate over, returns the next one.  
    // Modifies the state "this" to record  
    // that it has returned the element.  
    // If no elements remain, throw  
    // NoSuchElementException.  
    public Object next()  
        throws NoSuchElementException;  
  
    public void remove();  
}
```

Iterator vs. Enumeration

- Java provides another interface **Enumeration** for iterating over a collection.
- **Iterator** is
 - newer (since JDK 1.2)
 - has shorter method names
 - has a **remove()** method to remove elements from a collection during iteration
- **Iterator** **Enumeration**

| | |
|------------------|--------------------------|
| hasNext() | hasMoreElements() |
| next() | nextElement() |
| remove() | - |
- **Iterator** is recommended for newer implementations.

Example Loop controlled by `next()`

```
private Payroll payroll = new Payroll();  
...  
public void decreaseAllPayroll() { //by 10%  
    Iterator it = payroll.getIterator();  
    while (it.hasNext()) {  
        Employee e = (Employee) it.next();  
        double salary = e.getSalary();  
        e.setSalary(salary*.9);  
    }  
}
```

Implementing an Iterator

```
public class Payroll {  
    private Employee[] employees;  
    private int num_employees;  
    ...  
    // An iterator to loop through all Employees  
    public Iterator getIterator() {  
        return new EmplGen();  
    }  
    ...  
    private class EmplGen implements Iterator {  
        // see next slide  
        ...  
    }  
}
```

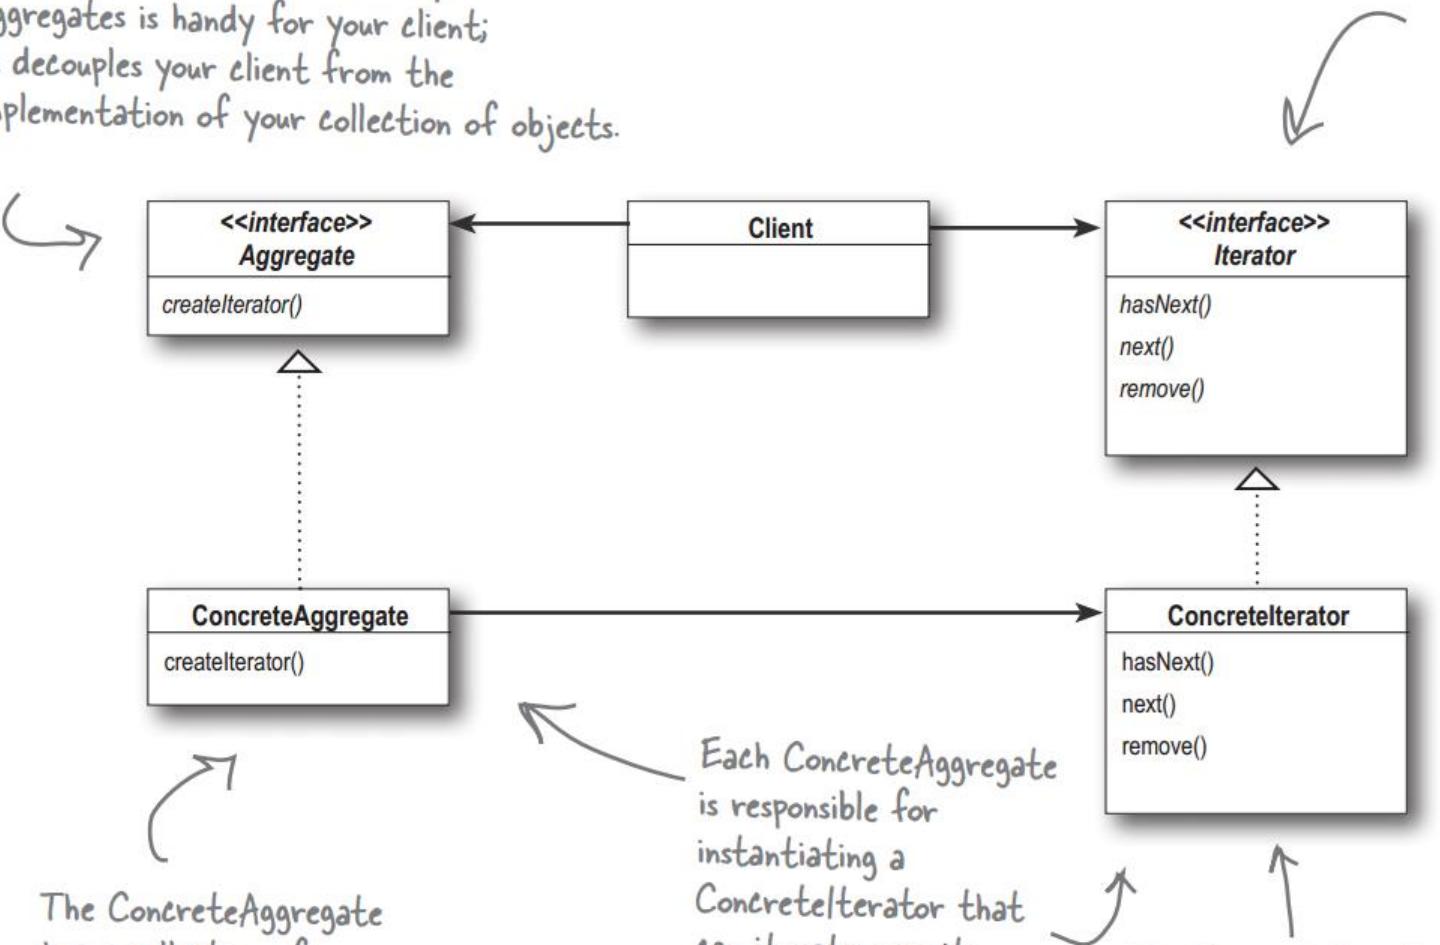

Implementing an Iterator

```
private class EmplGen implements Iterator {  
    private int n = 0; // state of iteration captured by index n  
  
    public boolean hasNext() { // returns true if there is an element left to iterate over  
        return n < num_employees;  
    }  
  
    public Object next() throws NoSuchElementException {  
        Object obj;  
        if (n < num_employees) {  
            obj = employees[n]; // returns the next element in the iteration sequence  
            n++;  
            return obj;  
        }  
        else throw new NoSuchElementException  
            ("No More Employees");  
    }  
}
```

Implementing an Iterator

```
public Object remove() {
    Object obj;
    if (n < num_employees) {
        obj = employees[n];
        // shift left all the elements from n+1...num_employees
        for(int i=n+1; i<num_employees; i++)
            employees[i-1] = employees[i];
        num_employees--;
        return obj;
    }
    else
        throw new NoSuchElementException("No More Employees");
}
```

Having a common interface for your aggregates is handy for your client; it decouples your client from the implementation of your collection of objects.

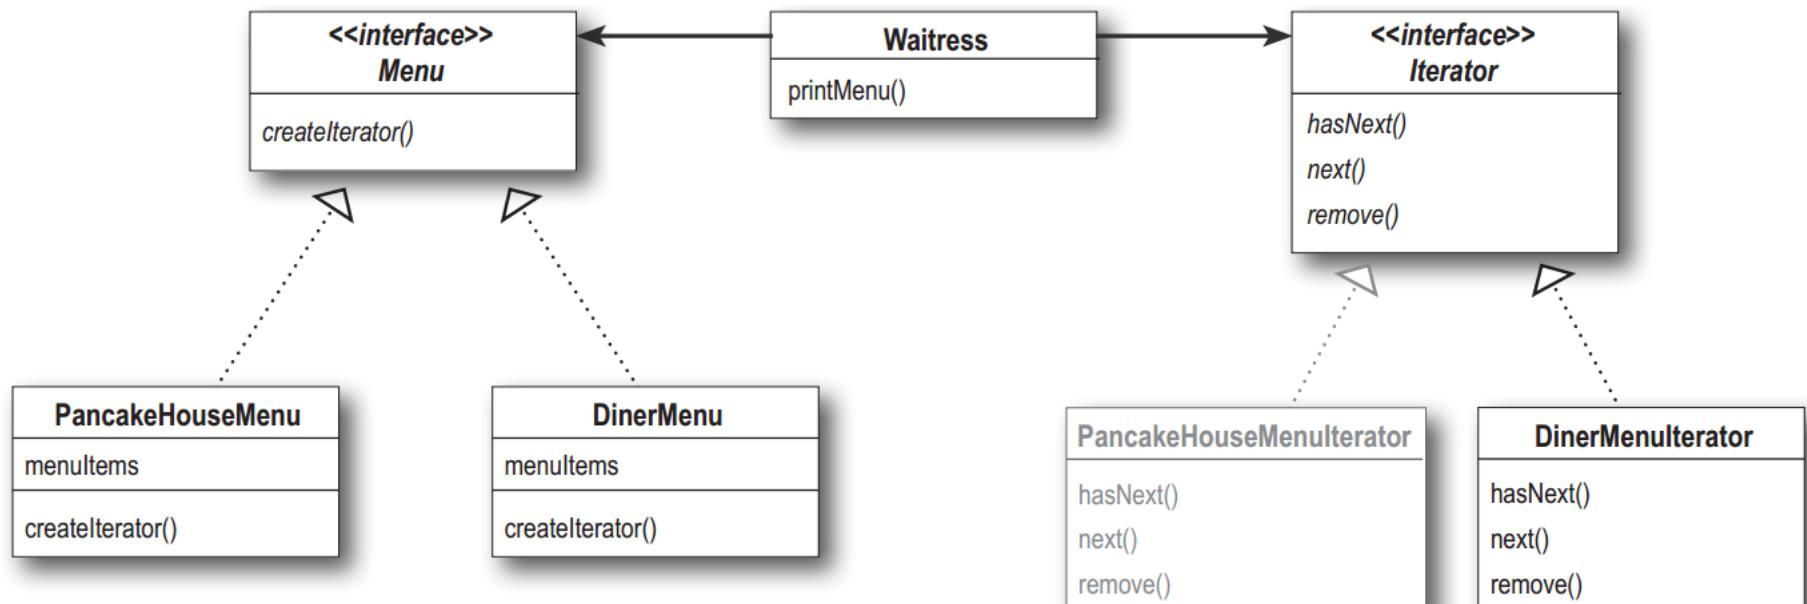

The ConcreteAggregate has a collection of objects and implements the method that returns an Iterator for its collection.

The Iterator interface provides the interface that all iterators must implement, and a set of methods for traversing over elements of a collection. Here we're using the java.util.Iterator. If you don't want to use Java's Iterator interface, you can always create your own.

The Iterator Pattern

Example: Pancake House and Diner Merger (they use different internal data structures: array vs. ArrayList)

```
import java.util.ArrayList; // Waitress.java
import java.util.List;
import java.util.Iterator;

interface Menu<E> {
    public Iterator<E> getIterator();
}

class PancakeHouseMenu<E> implements Menu<E> {
    private List<E> food;

    public PancakeHouseMenu() {
        food = new ArrayList<E>();
    }

    public void addFood(E food) {
        this.food.add(food);
    }

    public PancakeHouseMenuIterator<E> getIterator() {
        return new PancakeHouseMenuIterator<E>(food);
    }
}
```

```
class PancakeHouseMenuIterator<E> implements Iterator<E> {  
    private List<E> food;  
    private int position;  
    public PancakeHouseMenuIterator(List<E> food) {  
        this.food = food;  
    }  
    @Override  
    public boolean hasNext() {  
        if(position < food.size() && this.food.get(position) !=null){  
            return true;  
        } else {  
            return false;  
        }  
    }  
    @Override  
    public E next() {  
        return food.get(position++);  
    }  
    @Override  
    public void remove() {  
        this.food.remove(position);  
    }  
}
```

```
class DinerMenu<E> implements Menu<E> {
    private E[] food;
    int size = 0;

    public DinerMenu() {
        food = (E[]) (new Object[10]);
    }

    public void addFood(E food) {
        this.food[size++] = food;
    }

    public DinerMenuIterator<E> getIterator() {
        return new DinerMenuIterator<E>(food);
    }
}
```

```
class DinerMenuIterator<E> implements Iterator<E> {
    private E[] food;
    private int position;
    public DinerMenuIterator(E[] food) {
        this.food = food;
    }
    @Override
    public boolean hasNext() {
        if(position < food.length && this.food[position] !=null) {
            return true;
        } else {
            return false;
        }
    }
    @Override
    public E next() {
        return food[position++];
    }
    @Override
    public void remove() {
        // ToBeImplemented
    }
}
```

```
public class Waitress {  
    Menu pancakeHouseMenu;  
    Menu dinerMenu;  
    public Waitress(Menu pancakeHouseMenu, Menu dinerMenu) {  
        this.pancakeHouseMenu = pancakeHouseMenu;  
        this.dinerMenu = dinerMenu;  
    }  
    public void printMenu() {  
        Iterator pancakeIterator = pancakeHouseMenu.getIterator();  
        Iterator dinnerIterator = dinnerMenu.getIterator();  
        System.out.println("MENU\n---\nBREAKFAST");  
        printMenu(pancakeIterator);  
        System.out.println("\nLUNCH");  
        printMenu(dinnerIterator);  
    }  
    private void printMenu(Iterator iterator) {  
        while (iterator.hasNext()) {  
            MenuItem menuItem = (MenuItem) iterator.next();  
            System.out.print(menuItem.getName() + ", ");  
            System.out.print(menuItem.getPrice() + " -- ");  
            System.out.println(menuItem.getDescription());  
        }  
    }  
}
```

```
public static void main(String args[]) {  
    PancakeHouseMenu pancakeHouseMenu = new PancakeHouseMenu();  
    DinerMenu dinerMenu = new DinerMenu();  
    Waitress waitress = new Waitress(pancakeHouseMenu, dinerMenu);  
    waitress.printMenu();  
}  
}
```

```
class MenuItem {  
    String name;  
    String description;  
    boolean vegetarian;  
    double price;  
    public MenuItem(String name, String description,  
        boolean vegetarian, double price) {  
        this.name = name;  
        this.description = description;  
        this.vegetarian = vegetarian;  
        this.price = price;  
    }  
    public String getName() {  
        return name;  
    }  
    public String getDescription() {  
        return description;  
    }  
    public double getPrice() {  
        return price;  
    }  
    public boolean isVegetarian() {  
        return vegetarian;  
    }  
}
```

Common Design Patterns

Creational

- Factory
- Singleton
- Builder
- Prototype

Structural

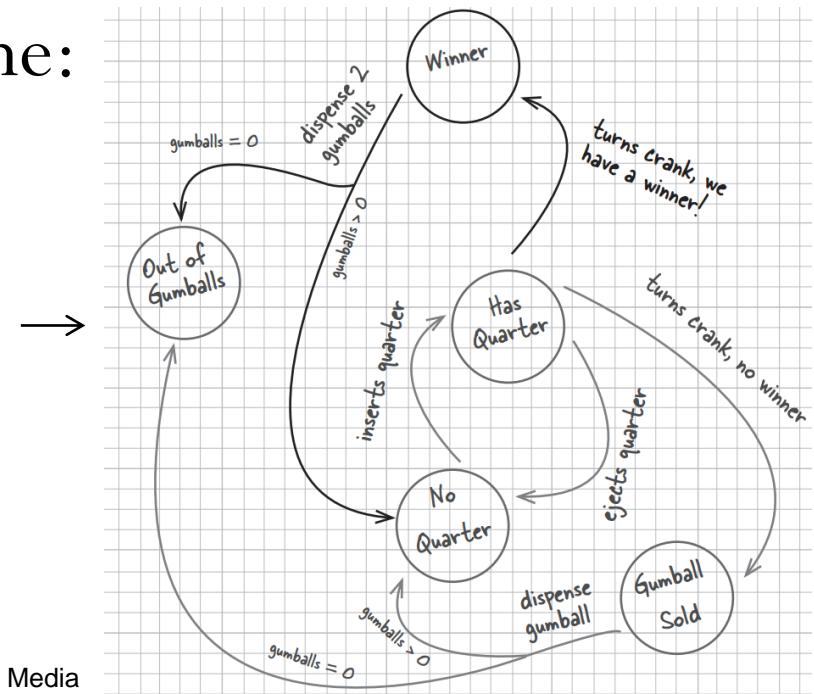

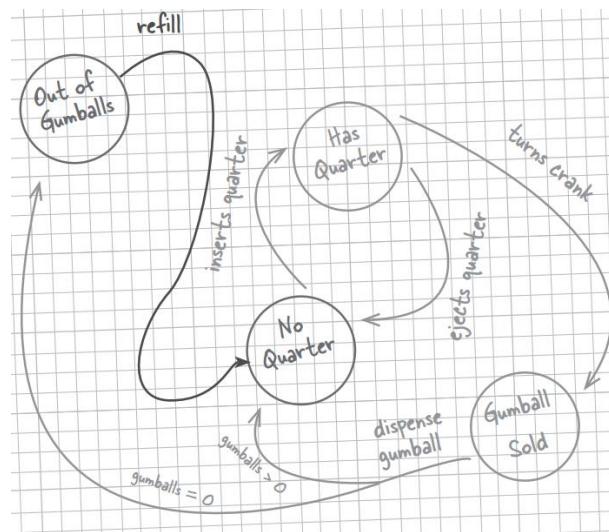

- Decorator
- Adapter
- Facade
- Flyweight
- Bridge

Behavioral

- **Strategy**
- **Template**
- **Observer**
- **Command**
- **Iterator**
- **State**

The State Pattern

- It is used to encapsulate varying behavior for the same routine based on an object's state object.
- If we model the state machine with constants, it is difficult to change it later.
- E.g., modify a gumball machine:

(c) Paul Fodor & O'Reilly Media

```
// GumballMachine.java
```

```
interface GumballMachineState{  
    void insertQuarter();  
    void ejectQuarter();  
    void turnCrank();  
    void dispense();  
    void refill(int balls);  
}
```

```
class HasQuarterState implements GumballMachineState {  
    private GumballMachine machine;  
    public HasQuarterState(GumballMachine machine) {  
        this.machine = machine;  
    }  
    @Override  
    public void insertQuarter() {  
        System.out.println("You already inserted a quarter");  
    }  
    @Override  
    public void ejectQuarter() {  
        System.out.println("Quarter ejected");  
        this.machine.setState(machine.getNoQuarterState());  
    }  
    @Override  
    public void turnCrank() {  
        System.out.println("You turned crank!");  
        machine.setState(machine.getSoldState());  
        machine.dispense();  
    }  
    @Override  
    public void dispense() {  
        System.out.println("You have to turn the crank first!");  
    }  
    @Override  
    public void refill(int balls) {  
        System.out.println("Can only refill if sold out.");  
    }  
}
```

```
class SoldState implements GumballMachineState {  
    private GumballMachine machine;  
    public SoldState(GumballMachine machine) {  
        this.machine = machine;  
    }  
    @Override  
    public void insertQuarter() {  
        System.out.println("Wait a second ... you are getting a gumball.");  
    }  
    @Override  
    public void ejectQuarter() {  
        System.out.println("Sorry, you already turned the crank.");  
    }  
    @Override  
    public void turnCrank() {  
        System.out.println("You already turned the crank. ");  
    }  
    @Override  
    public void dispense() {  
        this.machine.releaseBall();  
        if(machine.getCount() > 0) {  
            this.machine.setState(machine.getNoQuarterState());  
        } else {  
            System.out.println("Oops ... out of gumballs");  
            machine.setState(machine.getSoldOutState());  
        }  
    }  
    @Override  
    public void refill(int balls) {  
        System.out.println("Can only refill if sold out.");  
    }  
}
```

```
class SoldOutState implements GumballMachineState {  
    private GumballMachine machine;  
    public SoldOutState(GumballMachine machine) {  
        this.machine = machine;  
    }  
    @Override  
    public void insertQuarter() {  
        System.out.println("Machine sold out. You cannot insert a quarter");  
    }  
    @Override  
    public void ejectQuarter() {  
    }  
    @Override  
    public void turnCrank() {  
    }  
    @Override  
    public void dispense() {  
    }  
    @Override  
    public void refill(int balls) {  
        this.machine.setCount(balls);  
        this.machine.setState(this.machine.getNoQuarterState());  
    }  
}
```

```
class NoQuarterState implements GumballMachineState {  
    private GumballMachine machine;  
    public NoQuarterState(GumballMachine machine) {  
        this.machine = machine;  
    }  
    @Override  
    public void insertQuarter() {  
        System.out.println("You inserted a quarter");  
        this.machine.setState(machine.getHasQuarterState());  
    }  
    @Override  
    public void ejectQuarter() {  
        System.out.println("You haven't inserted a quarter!");  
    }  
    @Override  
    public void turnCrank() {  
        System.out.println("Please insert quarter first!");  
    }  
    @Override  
    public void dispense() {  
    }  
    @Override  
    public void refill(int balls) {  
        System.out.println("Can only refill if sold out.");  
    }  
}
```

```
public class GumballMachine {  
    private GumballMachineState hasQuarterState;  
    private GumballMachineState noQuarterState;  
    private GumballMachineState soldOutState;

    machine.insertQuarter();  
    machine.turnCrank();  
  
    machine.turnCrank();  
    machine.insertQuarter();  
    machine.dispense();  
    machine.turnCrank();  
  
    machine.insertQuarter();  
    machine.turnCrank();  
  
    machine.insertQuarter();  
    machine.refill(2);  
    machine.insertQuarter();  
    System.out.println(machine.getCount());  
    machine.turnCrank();  
    System.out.println(machine.getCount());  
}  
}
```

- You inserted a quarter
- You turned crank!
- A gumball comes rolling down the slot!
- Please insert quarter first!
- You inserted a quarter
- You have to turn the crank first!
- You turned crank!
- A gumball comes rolling down the slot!
- You inserted a quarter
- You turned crank!
- A gumball comes rolling down the slot!
- Oops ... out of gumballs
- Machine sold out. You cannot insert a quarter
- You inserted a quarter
- 2
- You turned crank!
- A gumball comes rolling down the slot!
- 1

```
interface TrafficLightState {                                // TrafficLight.java
    void switchOrange();
    void switchRed();
    void switchGreen();
}

class GreenState implements TrafficLightState {
    private TrafficLight light;
    public GreenState(TrafficLight light) {
        this.light = light;
    }
    @Override
    public void switchGreen() {
        System.out.println("Light is already green!");
    }
    @Override
    public void switchOrange() {
        light.setState(this.light.getOrangeState());
        System.out.println("Light switched to orange!");
    }
    @Override
    public void switchRed() {
        System.out.println("First switch the light to orange");
    }
}
```

```
class OrangeState implements TrafficLightState {  
    private TrafficLight light;  
    public OrangeState(TrafficLight light) {  
        this.light = light;  
    }  
    @Override  
    public void switchGreen() {  
        System.out.println("The light has to become red first!");  
    }  
    @Override  
    public void switchOrange() {  
        System.out.println("Light is already orange!");  
    }  
    @Override  
    public void switchRed() {  
        System.out.println("Light switched to red.");  
        this.light.setState(this.light.getRedState());  
    }  
}
```

```
class RedState implements TrafficLightState {  
    private TrafficLight light;  
    public RedState(TrafficLight light) {  
        this.light = light;  
    }  
    @Override  
    public void switchGreen() {  
        System.out.println("Light switched to green");  
        this.light.setState(this.light.getGreenState());  
    }  
    @Override  
    public void switchOrange() {  
        System.out.println("First switch the light to green");  
    }  
    @Override  
    public void switchRed() {  
        System.out.println("Light is already red.");  
    }  
}
```

```
public class TrafficLight {  
    private TrafficLightState redState;  
    private TrafficLightState orangeState;  
    private TrafficLightState greenState;  
    private TrafficLightState state;  
    public TrafficLight() {  
        redState = new RedState(this);  
        orangeState = new OrangeState(this);  
        greenState = new GreenState(this);  
        state = this.getRedState();  
    }  
    public void switchGreen() {  
        state.switchGreen();  
    }  
    public void switchOrange() {  
        state.switchOrange();  
    }  
    public void switchRed() {  
        state.switchRed();  
    }  
    public TrafficLightState getRedState() {  
        return redState;  
    }  
}
```

```
public TrafficLightState getOrangeState() {  
    return orangeState;  
}  
public TrafficLightState getGreenState() {  
    return greenState;  
}  
public void setState(TrafficLightState state) {  
    this.state = state;  
}  
public static void main(String[] args) {  
    TrafficLight light = new TrafficLight();  
    light.switchOrange();  
    light.switchGreen();  
    light.switchRed();  
    light.switchOrange();  
    light.switchOrange();  
    light.switchRed();  
}  
}
```

- First switch the light to green
- Light switched to green
- First switch the light to orange
- Light switched to orange!
- Light is already orange!
- Light switched to red.

Design Patterns

- Many other design patterns:
 - Concurrency patterns:
 - Monitor object: An object whose methods are subject to mutual exclusion, thus preventing multiple objects from erroneously trying to use it at the same time.
 - Reactor: A reactor object provides an asynchronous interface to resources that must be handled synchronously.
 - Read-write lock: Allows concurrent read access to an object, but requires exclusive access for write operations.
 - Scheduler: Explicitly control when threads may execute single-threaded code.
 - Other: Active object, Balking, Event-based asynchronous, Guarded suspension, Join, Lock, Monitor, Proactor, Read write lock, Thread Pool, Thread-local storage
 - Architectural patterns: n-tier, Specification, Publish-subscribe, Service, Locator...
- Use the design patterns, BUT inappropriate use of patterns may unnecessarily increased complexity.

Other languages have other patterns.

Conclusion

Conclusion for this course

- That is all!
 - I hope that this course has sparked a lot of ideas and encourages you to exercise programming
- Thank you!
