## Hash Functions номе

## Hash function

## Definition

- A hash function is a function that maps arbitrary size data to fixed size data.

## Cryptographic hash function

## Input

| cryptographic <br> hash <br> function |
| :---: |$\longrightarrow$| DFCD | 3454 | BBEA | 788A | $751 A$ |

## Properties of an ideal cryptographic hash function

- Deterministic and fast
- Computing message from hash value is infeasible
- Computing two messages having same hash value is infeasible
- Tiny change in message must change the hash value drastically

## Applications of hashing

- Web page search using URLs
- Password verification
- Symbol tables in compilers
- Filename-filepath linking in operating systems
- Plagiarism detection using Rabin-Karp string matching algorithm
- English dictionary search
- Used as part of the following concepts:
- finding distinct elements
- counting frequencies of items
- finding duplicates
- message digests
- commitment
- Bloom filters

## Password authentication

## Hash Tables $\boldsymbol{\text { Home }}$

## Hash table

- A hash table is a data structure to implement dictionary ADT
- A hash table is an efficient implementation of a set/multiset/map/multimap.
- A hash table performs insert, delete, and search operations in constant expected time.

## Balanced search trees vs. Hash tables

- Balanced search tree is ideal for sorted collection
- Hash table is ideal for unsorted collection

|  |  | Balanced tree <br> Operations <br> (worst) |  | Hash table <br> (avg.) |  | (worst) |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| Sorting-unrelated <br> operations | Insert | $\mathcal{O}(\log n)$ | $\mathcal{O}(1)$ | $\mathcal{O}(n)$ |  |  |
|  | Delete | $\mathcal{O}(\log n)$ | $\mathcal{O}(1)$ | $\mathcal{O}(n)$ |  |  |
|  | Search | $\mathcal{O}(\log n)$ | $\mathcal{O}(1)$ | $\mathcal{O}(n)$ |  |  |
| Sorting-related | Sort | $\mathcal{O}(n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Minimum | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Maximum | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Predecessor | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Successor | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Range-Minimum | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Range-Maximum | $\mathcal{O}(\log n)$ | $\boldsymbol{x}$ |  |  |  |
|  | Range-Sum | $\mathcal{O}(n)$ | $\boldsymbol{x}$ |  |  |  |

## Hash table

## Hash table

Key space

- A hash function is a mapping from arbitrary objects to the set of indices $[0, N-1]$.
- The key-value pair $(k, v)$ in stored at $A[\mathcal{H}(k)]$ in the hash table.

## Hash table

## Questions

1. How can keys of arbitrary objects be mapped to array indices that are whole numbers?
2. How can an infinite number of keys be mapped to a finite number of indices?
3. What are the pros/cons of hash tables w.r.t. balanced trees?
4. What are the properties of an ideal hash function?
5. Is there one practical hash function that is best for all input?
6. What is the hash function used in Java?
7. Will there be collisions during hashing? If yes, how can we avoid collisions?
8. Is there a relation between table size and the number of items?
9. Why (key, value) pairs? Why not tuples?

## Encoding of information

Problem

- How can keys of arbitrary objects be mapped to array indices that are whole numbers?

## Encoding of information

## Problem

- How can keys of arbitrary objects be mapped to array indices that are whole numbers?

Key space

String space

## Two stages of hash function

Problem

- How can an infinite number of keys be mapped to a finite number of indices?

## Two stages of hash function

## Problem

- How can an infinite number of keys be mapped to a finite number of indices?

| Arbitrary key $k$ | Stage 1 | $-\infty$ | Stage 2 | 0 |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\vdots$ |  | 1 |
|  |  | -1 |  | 2 |
|  | Hash code | 0 | Compression | 3 |
|  |  | 1 |  | 4 |
|  |  | : |  | ! |
|  |  | $\infty$ |  | $N-1$ |
|  |  | ntege |  | Indices |

Key space

## Stage 1 of hash function: Hash code

- Consider bits as integer.

Hashcode(byte | short | char) = 32-bit int
$\triangleright$ upscaling
Hashcode(float) $=32$-bit int $\quad \triangleright$ change representation Hashcode(double) $=32$-bit int
$\triangleright$ downscaling $\operatorname{Hashcode}\left(x_{0}, x_{1}, \ldots, x_{n-1}\right)=x_{0}+x_{1}+\cdots+x_{n-1}$
$\triangleright$ sum
$\operatorname{Hashcode}\left(x_{0}, x_{1}, \ldots, x_{n-1}\right)=x_{0} \oplus x_{1} \oplus \cdots \oplus x_{n-1}$
$\triangleright$ xor

- Polynomial hash codes.

Hashcode $\left(x_{0}, x_{1}, \ldots, x_{n-1}\right)=$
$\square$ $\triangleright$ polynomial

- Cyclic-shift hash codes.
$\operatorname{Hashcode}_{k}(x)=\operatorname{Rotate}(x, k$ bits)
$\triangleright$ cyclic-shift e.g.: $\operatorname{Hashcode}_{2}(111000)=100011$

## Stage 2 of hash function: Compression function

A good compression function minimizes the number of collisions for a given set of distinct hash codes.

- Division method.

Compression $(i)=i \% N$
$\triangleright$ remainder
$N \geq 1$ is the size of the bucket array.
Often, $N$ being prime "spreads out" the distribution of primes.
Ex. 1: Insert codes $\{200,205, \ldots, 600\}$ into $N$-sized array.
Which is better: $N=100$ or $N=101$ ?
Ex. 2: Insert multiple codes $\{a N+b\}$ into $N$-sized array.
Which is better: $N=$ prime or $N=$ non-prime?

- Multiply-Add-and-Divide (MAD) method.

Compression $(i)=((a i+b) \% p) \% N \quad \triangleright$ remainder
$N \geq 1$ is the size of the bucket array.
$p$ is a prime number larger than $N$.
$a, b$ are random integers from the range $[0, p-1]$ with $a>0$.
Usually eliminates repeated patterns in the set of hash codes.

## English dictionary

## Problem

- How do you implement the English dictionary search such that searching for a word takes $\mathcal{O}(1)$ time on an average?

Hash space

## Collisions

Entries
Hashes

## Collision-handling schemes

There are two major collision-handling schemes or collision-resolution strategies.

| Collision-handling scheme | Features |
| :--- | :--- |
| Separate chaining | Extra space (for secondary data structures) <br> Simpler implementation |
| Open addressing | No extra space <br> More complicated implementation |

## Separate chaining

- Have each bucket $A[j]$ store its own secondary container.
- We use secondary data structures (e.g. array list, linked list, balanced search trees, etc) for each bucket.

## Separate chaining (via arraylist/linkedlist)

| $\operatorname{PUT}(($ key, value)) |  |
| :---: | :---: |
| 1. hash $\leftarrow \operatorname{Hash}(k e y)$ <br> 2. $A[h a s h] . \operatorname{ADDLAST}((k e y, v a l u e))$ | $\triangleright A[h a s h]$ is a linked list |
| GET(key) |  |
| 1. hash $\leftarrow \operatorname{HASH}(k e y)$ <br> 2. return $A[h a s h]$.GET (key) | $\triangleright$ returns value |
| Remove(key) |  |
| 1. hash $\leftarrow \operatorname{HASH}(k e y)$ <br> 2. return $A[h a s h]$.Remove(key) | $\triangleright$ returns removed value |

## Open addressing

- All entries are stored in the bucket array itself.
- Strict requirement: Load factor must be at most 1 .
- Useful in applications where there are space constraints, e.g.: smartphones and other small devices.
- Iteratively search the bucket $A[(\operatorname{HASH}(k e y)+f(i)) \% N]$ for $i=0,1,2,3, \ldots$ until finding an empty bucket.

| Scheme | Function |
| :--- | :--- |
| Linear probing | $f(i)=i$ |
| Quadratic probing | $f(i)=i^{2}$ |
| Double hashing | $f(i)=i \cdot \operatorname{HaSH} 2(k e y)$ |
|  | e.g. HaSH2 $($ key $)=p-($ key $\% p)$ for prime $p<N$. |
|  | Here $N$ should be a prime number. |
| Random generator | $f(i)=\operatorname{RaNDOM}(i, \operatorname{HaSH}($ key $))$ |

## Open addressing: Linear probing: Put

- Suppose $\operatorname{Hash}($ key $)=$ key $\% 10$

| Put |  |  | Array |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Key | $\rightarrow$ | Hash | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
|  | $\rightarrow$ | 8 |  |  |  |  |  |  |  |  | 18 |  |
|  | $\rightarrow$ | 1 |  | 41 |  |  |  |  |  |  | 18 |  |
| 22 | $\rightarrow$ | 2 |  | 41 | 22 |  |  |  |  |  | 18 |  |
| 32 | $\rightarrow$ | 2 |  | 41 | 22 |  |  |  |  |  | 18 |  |
| (2 probes) |  |  |  | 41 | 22 | 32 |  |  |  |  | 18 |  |
| $\underbrace{\rightarrow}_{(2 \text { probes) }} \quad 8$ |  |  |  | 41 | 22 | 32 |  |  |  |  | 18 |  |
|  |  |  |  | 41 | 22 | 32 |  |  |  |  | 18 | 98 |
|  | $\rightarrow$ |  |  | 41 | 22 | 32 |  |  |  |  | 18 | 98 |
|  |  |  |  | 41 | 22 | 32 |  |  |  |  | 18 | 98 |
| (3 probes) |  |  | 58 | 41 | 22 | 32 |  |  |  |  | 18 | 98 |
| 78 | $\rightarrow$ | 8 | How many probes are required to insert 78? |  |  |  |  |  |  |  |  |  |

## Open addressing: Linear probing: Remove

- Suppose $\operatorname{Hash}(k e y)=$ key $\% 10$

| Remove Key | Array |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| - | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
| 58 | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
|  |  | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
| 19 |  | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
|  | Hence, we cannot simply remove a found entry. |  |  |  |  |  |  |  |  |  |

| Remove |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Key | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| - | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
| 58 | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
| 19 | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
|  | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
|  | 58 | 41 | 22 | 32 | 78 | 19 |  |  | 18 | 98 |
|  | Replace the deleted entry with the defunct object. |  |  |  |  |  |  |  |  |  |

## Open addressing: Linear probing

```
Put((key, value))
1. hash \(\leftarrow \operatorname{HASH}(k e y) ; i \leftarrow 0\)
2. while (hash \(+i\) ) \(\% N \neq\) null and \(i<N\) do \(i \leftarrow i+1\)
3. if \(i=N\) then throw Bucket array is full
4. else \(A[(h a s h+i) \% N] \leftarrow(k e y\), value \()\)
    GET(key)
    1. hash \(\leftarrow \operatorname{Hash}(\) key \() ; i \leftarrow 0\)
    2. while (hash \(+i\) ) \(\% N \neq\) null and \(i<N\) do
    3. index \(\leftarrow(\) hash \(+i) \% N\)
    4. if \(A[\) index].key \(=k e y\) then return \(A[\) index].value
    5. \(\quad i \leftarrow i+1\)
    6. return null
    Remove(key)
    1. index \(\leftarrow\) FindSlotForRemoval(key)
    2. if index \(<0\) then return null
    3. value \(\leftarrow A[\) index \(]\).value \(; A[\) index \(] \leftarrow\) defunct \(; n \leftarrow n-1\)
    4. return value
```

## Complexity

- Suppose $N=$ bucket array size and $n=$ number of entries.
- Ratio $\lambda=n / N$ is called the load factor of the hash table.
- If $\lambda>1$, rehash. Make sure $\lambda<1$.
- Assuming good hash function, expected size of bucket is $\mathcal{O}(\lceil\lambda\rceil)$.
- Separate chaining: Maintain $\lambda<0.75$

Open addressing: Maintain $\lambda<0.5$

- Assuming good hash function and $\lambda \in \mathcal{O}(1)$, complexity of put, get, and remove is $\mathcal{O}(1)$ expected time.

## Applications

## Symbol tables in compilers

```
double foo(int count)
{
        double sum = 0.0;
        for (int i = 1; i <= count; i++)
            sum += i;
        return sum;
}
```

| Symbol | Type | Scope |
| :--- | :--- | :--- |
| foo | function, double | global |
| count | int | function parameter |
| sum | double | block local |
| i | int | for-loop statement |
